Contents

1 INTRODUCTION 19
1 Introduction 21
1.1 Programming and computational thinking 21
1.1.1 History 21
1.1.2 Is programming science, art, or craft? 22
1.1.3 Computational thinking 23
1.1.4 Hardware 25
1.1.5 Algorithms 25
1.2 About the choice of language 26
2 Warming up 29
2.1 Programming environment 29
2.1.1 Language support in your editor 29
2.2 Compiling 30
2.3 Your environment 30
3 Teachers guide 31
3.1 Justification 31
3.2 Timeline for a C++/F03 course 32
3.2.1 Advanced topics 32
3.2.2 Project-based teaching 32
3.2.3 Choice: Fortran or advanced topics 32
3.3 Scaffolding 32
3.4 Grading guide 34
3.4.1 Code layout and naming 34
3.4.2 Basic elements 34
3.4.3 Conditionals 35
3.4.4 Looping 35
3.4.5 Functions 35
3.4.6 Scope 35
3.4.7 Structures 35
3.4.8 Classes 36
3.4.9 Arrays and vectors 36
3.4.10 Strings 36
3.4.11 Other remarks 36

12 Strings 159
12.1 Characters 159
12.2 Basic string stuff 159
12.3 String streams 163
12.4 Advanced topics 163
12.4.1 Conversation to/from string 163
12.4.2 Unicode 163
12.5 C strings 164
13 Input/output 165
13.1 Screen output 165
13.1.1 Floating point output 168
13.1.2 Saving and restoring settings 169
13.2 File output 170
13.3 Output your own classes 170
13.4 Output buffering 171
13.5 Input 171
13.5.1 File input 172
13.5.2 Input streams 173
14 Iterators, Algorithms, Ranges 175
14.1 Iterators 175
14.2 Algorithms 175
14.3 Ranges 176
14.3.1 Infinite sequences 178
15 References 179
15.1 Reference 179
15.2 Pass by reference 179
15.3 Reference to class members 180
15.4 Reference to array members 182
15.5 rvalue references 183
16 Pointers 185
16.1 The ‘arrow’ notation 185
16.2 Making a shared pointer 186
16.2.1 Pointers and arrays 187
16.2.2 Smart pointers versus address pointers 189
16.3 Garbage collection 189
16.4 More about pointers 190
16.4.1 Get the pointed data 190
16.5 Advanced topics 191
16.5.1 Unique pointers 191
16.5.2 Base and derived pointers 191
16.5.3 Shared pointer to ‘this’ 191
16.5.4 Weak pointers 192
16.5.5 Null pointer 193
16.5.6 Opaque pointer 193
16.5.7 Pointers to non-objects 193
16.6 Smart pointers vs C pointers 194
## CONTENTS

17 C-style pointers and arrays 195
17.1 What is a pointer 195
17.2 Pointers and addresses, C style 195
17.3 Arrays and pointers 197
17.4 Pointer arithmetic 199
17.5 Multi-dimensional arrays 199
17.6 Parameter passing 199
17.6.1 Allocation 200
17.6.2 Use of new 202
17.7 Memory leaks 203
17.8 Const pointers 203
18 Const 205
18.1 Const arguments 205
18.2 Const references 205
18.2.1 Const references in range-based loops 207
18.3 Const methods 207
18.4 Overloading on const 207
18.5 Const and pointers 208
18.5.1 Old-style const pointers 209
18.6 Mutable 210
18.7 Compile-time constants 212
19 Prototypes and header files 213
19.1 Prototypes for functions 213
19.1.1 Separate compilation 214
19.1.2 Header files 215
19.1.3 C and C++ headers 215
19.2 Prototypes for class methods 216
19.3 Header files and templates 217
19.4 Namespaces and header files 217
19.5 Global variables and header files 217
19.6 Modules 218
20 Namespaces 219
20.1 Solving name conflicts 219
20.1.1 Namespace header files 220
20.2 Best practices 221
21 Preprocessor 223
21.1 Include files 223
21.1.1 Kinds of includes 223
21.1.2 Search paths 224
21.2 Textual substitution 224
21.2.1 Dynamic definition of macros 225
21.2.2 A new use for ‘using’ 225
21.2.3 Parametrized macros 225
21.3 Conditionals 226
21.3.1 Check on a value 226
21.3.2 Check for macros 226
30.1 Source format 283
30.2 Compiling Fortran 284
30.3 Main program 284
30.3.1 Program structure 284
30.3.2 Statements 285
30.3.3 Comments 285
30.4 Variables 285
30.4.1 Declarations 286
30.4.2 Precision 286
30.4.3 Initialization 287
30.5 Quick comparison Fortran vs C++ 288
30.5.1 Statements 288
30.5.2 Input/Output, or I/O as we say 288
30.5.3 Expressions 288
30.6 Complex numbers 289
30.7 Review questions 290
31 Conditionals 293
31.1 Forms of the conditional statement 293
31.2 Operators 293
31.3 Select statement 294
31.4 Boolean variables 294
31.5 Review questions 295
32 Loop constructs 297
32.1 Loop types 297
32.2 Interruptions of the control flow 298
32.3 Implied do-loops 299
32.4 Review questions 300
33 Scope 301
33.1 Scope 301
33.1.1 Variables local to a program unit 301
33.1.2 Variables in an internal procedure 302
34 Procedures 303
34.1 Subroutines and functions 303
34.2 Return results 305
34.2.1 The ‘result’ keyword 307
34.2.2 The ‘contains’ clause 307
34.3 Arguments 308
34.4 Types of procedures 309
34.5 More about arguments 309
35 String handling 311
35.1 String denotations 311
35.2 Characters 311
35.3 Strings 311
35.4 Strings versus character arrays 312
35.5 Formatted I/O 312
35.5.1 Format letters 312

PART I

INTRODUCTION
Chapter 1

Introduction

1.1 Programming and computational thinking

1.1.1 History

Earliest computers

Historically, computers were used for big physics calculations, for instance, atom bomb calculations (Robert Oppenheimer and John von Neumann)

Hands-on programming

Very early computers such as ENIAC were hardwired later became ‘stored program’ computer.

see http://eniacprogrammers.org/
1. Introduction

Program entry
Later programs were written on punchcards

The first programming language
Initial programming was about translating the math formulas; after a while they made a language for that: FORmula TRANslatin

Programming is everywhere
Programming is used in many different ways these days.
- You can make your own commands in Microsoft Word.
- You can make apps for your smartphone.
- You can solve the riddles of the universe using big computers.

This course is aimed at people in the last category.

1.1.2 Is programming science, art, or craft?
In the early days of computing, hardware design was seen as challenging, while programming was little more than data entry. The fact that Fortran stands for ‘formula translation’ speaks of this: once you have
the math, programming is nothing more than translating the math into code. The fact that programs could have subtle errors, or bugs, came as quite a surprise.

The fact that programming was not as highly valued also had the side-effect that many of the early programmers were women. Two famous examples were Navy Rear-admiral Grace Hopper, inventor of the Cobol language, and Margaret Hamilton who led the development of the Apollo program software. This situation changed after the 1960s and certainly with the advent of PCs¹.

There are scientific aspects to programming:

- Algorithms and complexity theory have a lot of math in them.
- Programming language design is another mathematically tinged subject.

But for a large part programming is a discipline. What constitutes a good program is a matter of taste. That does not mean that there aren’t recommended practices. In this course we will emphasize certain practices that we think lead to good code, as likewise will discourage you from certain idioms.

None of this is an exact science. There are multiple programs that give the right output. However, programs are rarely static. They often need to be amended or extended, or even fixed, if erroneous behaviour comes to light, and in that case a badly written program can be a detriment to programmer productivity. An important consideration, therefore, is intelligibility of the program, to another programmer, to your professor in this course, or even to yourself two weeks from now.

### 1.1.3 Computational thinking

#### Programming is not simple

Programs can get pretty big:

> Margaret Hamilton, director of the Software Engineering Division, the MIT Instrumentation Laboratory, which developed on-board software for the Apollo program.

It’s not just translating formulas anymore.

Translating ideas to computer code: computational thinking.

#### Computational thinking: elevator scheduling

Mathematical thinking:

- Number of people per day, speed of elevator ⇒ yes, it is possible to get everyone to the right floor.
- Distribution of people arriving etc. ⇒ average wait time.

---

*Victor Eijkhout*
1. Introduction

Sufficient condition $\neq$ existence proof.

Computational thinking: actual design of a solution

- Elevator scheduling: someone at ground level presses the button, there are cars on floors 5 and 10; which one do you send down?

Coming up with a strategy takes creativity!

Exercise 1.1. A straightforward calculation is the simplest example of an algorithm.

Calculate how many schools for hair dressers the US can sustain. Identify the relevant factors, estimate their sizes, and perform the calculation.

Exercise 1.2. Algorithms are usually not uniquely determined: there is more than one way solve a problem.

Four self-driving cars arrive simultaneously at an all-way-stop intersection. Come up with an algorithm that a car can follow to safely cross the intersection. If you can come up with more than one algorithm, what happens when two cars using different algorithms meet each other?

Computation and complexity

Looking up a name in the phone book

- start on page 1, then try page 2, et cetera
- or start in the middle, continue with one of the halves.

What is the average search time in the two cases?

Having a correct solution is not enough!

Programming languages are about ideas

A powerful programming language serves as a framework within which we organize our ideas. Every programming language has three mechanisms for accomplishing this:

- primitive expressions
- means of combination
- means of abstraction

Abelson and Sussman, The Structure and Interpretation of Computer Programs

Abstraction

- The elevator programmer probably thinks: ‘if the button is pressed’, not ‘if the voltage on that wire is 5 Volt’.
- The Google car programmer probably writes: ‘if the car before me slows down’, not ‘if I see the image of the car growing’.
- … but probably another programmer had to write that translation.

A program has layers of abstractions.

Abstraction is good

Abstraction means your program talks about your application concepts, rather than about numbers and
characters and such.

Your program should read like a story about your application; not about bits and bytes.

Good programming style makes code intelligible and maintainable.

(Bad programming style may lead to lower grade.)

**Trust him, he’s Dutch!**

The competent programmer is fully aware of the strictly limited size of his own skull; therefore he approaches the programming task in full humility, and among other things he avoids clever tricks like the plague — Edsger Dijkstra

**Data abstraction**

What is the structure of the data in your program?

Stack: you can only get at the top item

Queue: items get added in the back, processed at the front

A program contains structures that support the algorithm. You may have to design them yourself.

---

### 1.1.4 Hardware

**Do you have to know much about hardware?**

Yes, it’s there, but we don’t think too much about it in this course.

Advanced programmers know that hardware influences the speed of execution (see TACC’s ISTC course).

---

### 1.1.5 Algorithms

**What is an algorithm?**

An algorithm is a sequence of unambiguous instructions for solving a problem, i.e., for obtaining a required output for any legitimate input in a finite amount of time

The instructions are written in some language:

- We will teach you C++ and Fortran;
- the compiler translates those languages to machine language.
1. Introduction

Program steps

- Simple instructions: arithmetic.
- Complicated instructions: control structures
  - conditionals
  - loops

Program data

- Input and output data: to/from file, user input, screen output, graphics.
- Data during the program run:
  - Simple variables: character, integer, floating point
  - Arrays: indexed set of characters and such
  - Data structures: trees, queues
    * Defined by the user, specific for the application
    * Found in a library (big difference between C/C++)

1.2 About the choice of language

There are many programming languages, and not every language is equally suited for every purpose. In this book you will learn C++ and Fortran, because they are particularly good for scientific computing. And by ‘good’, we mean

- They can express the sorts of problems you want to tackle in scientific computing, and
- they execute your program efficiently.

There are other languages that may not be as convenient or efficient in expressing scientific problems. For instance, python is a popular language, but typically not the first choice if you’re writing a scientific program. As an illustration, here is simple sorting algorithm, coded in both C++ and python.

Comparing two languages

Python vs C++ on bubblesort:

```python
for i in range(n-1):
    for j in range(n-i-1):
        if numbers[j+1]<numbers[j]:
            swaptmp = numbers[j+1]
            numbers[j+1] = numbers[j]
            numbers[j] = swaptmp
```

```cpp
for (int i=0; i<n-1; i++)
    for (int j=0; j<n-1-i; j++)
        if (numbers[j+1]<numbers[j]) {
            int swaptmp = numbers[j+1];
            numbers[j+1] = numbers[j];
            numbers[j] = swaptmp;
        }
```

```
$ python bubblesort.py 5000
Elapsed time: 12.1030311584
$ ./bubblesort 5000
Elapsed time: 0.24121
```

But this ignores one thing: the sorting algorithm we just implemented is not actually a terribly good one, and in fact python has a better one built-in.
1.2. About the choice of language

The right language is not all

Python with quicksort algorithm:

```python
numpy.sort(numbers, kind='quicksort')
```

```python
[] python arraysort.py 5000
Elapsed time: 0.00210881233215
```

So that is another consideration when choosing a language: is there a language that already comes with the tools you need. This means that your application may dictate the choice of language. If you’re stuck with one language, don’t reinvent the wheel! If someone has already coded it or it’s part of the language, don’t redo it yourself.
1. Introduction
Chapter 2

Warming up

2.1 Programming environment

Programming can be done in any number of ways. It is possible to use an Integrated Development Environment (IDE) such as Xcode or Visual Studio, but for if you’re going to be doing some computational science you should really learn a Unix variant.

• If you have a Linux computer, you are all set.
• If you have an Apple computer, it is easy to get you going. You can use the standard Terminal program, or you can use a full X windows installation, such as XQuartz, which makes Unix graphics possible. This, and other Unix programs can be obtained through a package manager such as homebrew or macports.
• Microsoft Windows users can use putty but it is probably a better solution to install a virtual environment such as VMware (http://www.vmware.com/) or Virtualbox (https://www.virtualbox.org/).

Next, you should know a text editor. The two most common ones are vi and emacs.

2.1.1 Language support in your editor

The author of this book is very much in favour of the emacs editor. The main reason is its support for programming languages. Most of the time it will detect what language a file is written in, based on the file extension:

• cxx, cpp, cc for C++, and
• f90, F90 for Fortran.

If your editor somehow doesn’t detect the language, you can add a line at the top of the file:

// -*- c++ -*-

for C++ mode, and

! -*- f90 -*-

for Fortran mode.

Main advantages are automatic indentation (C++ and Fortran) and supplying block end statements (Fortran). The editor will also apply ‘syntax colouring’ to indicate the difference between keywords and variables.
2. Warming up

2.2 Compiling

The word ‘program’ is ambiguous. Part of the time it means the source code: the text that you type, using a text editor. And part of the time it means the executable, a totally unreadable version of your source code, that can be understood and executed by the computer. The process of turning your source code into an executable is called compiling, and it requires something called a compiler. (So who wrote the source code for the compiler? Good question.)

Here is the workflow for program development

1. You think about how to solve your program
3. You compile your code. That gives you an executable. Oh, make that: you try to compile, because there will probably be compiler errors: places where you sin against the language syntax.
4. You run your code. Chances are it will not do exactly what you intended, so you go back to the editing step.

2.3 Your environment

Exercise 2.1. Do an online search into the history of computer programming. Write a page, if possible with illustration, and turn this into a pdf file. Submit this to your teacher.
Chapter 3

Teachers guide

This book was written for a one-semester introductory programming course at The University of Texas at Austin, aimed primarily at students in the physical and engineering sciences. Thus, examples and exercises are as much as possible scientifically motivated. This target audience also explains the inclusion of Fortran.

This book is not encyclopedic. Rather than teaching each topic in its full glory, the author has taken a ‘good practices’ approach, where students learn enough of each topic to become a competent programmer. This serves to keep this book at a manageable length, and to minimize class lecture time, emphasizing lab exercises instead.

Even then, there is more material here than can be covered and practiced in one semester. If only C++ is taught, it is probably possible to cover the whole of Part II; for the case where both C++ and Fortran are taught, we have a suggested timeline below.

3.1 Justification

The chapters of Part II and Part III are presented in suggested teaching order. Here we briefly justify our (non-standard) sequencing of topics and outline a timetable for material to be covered in one semester. Most notably, Object-Oriented programming is covered before arrays and pointers come very late, if at all.

There are several thoughts behind this. For one, dynamic arrays in C++ are most easily realized through the std::vector mechanism, which requires an understanding of classes. The same goes for std::string.

Secondly, in the traditional approach, object-oriented techniques are taught late in the course, after all the basic mechanisms, including arrays. We consider OOP to be an important notion in program design, and central to C++, rather than an embellishment on the traditional C mechanisms, so we introduce it as early as possible.

Even more elementary, we emphasize range-based loops as much as possible over indexed loops, since ranges are increasing in importance in recent language versions.
3. Teachers guide

3.2 Timeline for a C++/F03 course

As remarked above, this book is based on a course that teaches both C++ and Fortran2003. Here we give the timeline used, including some of the assigned exercises.

For a one semester course of slightly over three months, two months would be spent on C++ (see table 3.1), after which a month is enough to explain Fortran. Remaining time will go to exams and elective topics.

3.2.1 Advanced topics

Depending on time availability, the topics in table 3.2 can be taught.

3.2.2 Project-based teaching

To an extent it is inevitable that students will do a number of exercises that are not connected to any earlier or later ones. However, to give some continuity, we have given some programming projects that students gradually build towards.

- prime Prime number testing, culminating in prime number sequence objects, and testing a corollary of the Goldbach conjecture. Chapter 52.
- geom Geometry related concepts; this is mostly an exercise in object-oriented programming. Chapter 53.
- infect The spreading of infectious diseases; these are exercises in object-oriented design. Students can explore various real-life scenarios. Chapter 54.
- pagerank The Google Pagerank algorithm. Students program a simulated internet, and explore pageranking, including ‘search engine optimization’. This exercise uses lots of pointers. Chapter 55.
- scheduling Exploration of concepts related to the Traveling Salesman Problem (TSP), with some modifications that model Amazon Prime.

Rather than including the project exercises in the didactic sections, each section of these projects list the prerequisite basic sections.

The project assignments give a fairly detailed step-by-step suggested approach. This acknowledges the theory of Cognitive Load [8].

Our projects are very much computation-based. A more GUI-like approach to project-based teaching is described in [7].

3.2.3 Choice: Fortran or advanced topics

After two months of grounding in OOP programming in C++, the Fortran lectures and exercises reprise this sequence, letting the students do the same exercises in Fortran that they did in C++. However, array mechanisms in Fortran warrant a separate lecture.

3.3 Scaffolding

As much as possible, when introducing a new topic I try to give a working code, with the first exercise being a modification of this code. At the root level of the repository is a directory skeletons, containing the example programs. In the above table, exercises are indicated for which a skeleton code is given.
### 3.3. Scaffolding

Table 3.1: Two-month lesson plan for C++; the annotation ‘(S)’ indicates that a skeleton code is available; ‘(T)’ indicates that a tester script is available.

### 3.4 Grading guide

Here are some general guidelines on things that should count as negatives when grading. These are all style points: a code using them may very well give the right answer, but they go against what is commonly considered good or clean code.

#### 3.4.1 Code layout and naming

Code should use proper indentation. Incorrect indentation deceives the reader.

Non-obvious code segments should be commented, but proper naming of variables and functions goes a long way towards making this less urgent.

#### 3.4.2 Basic elements

- Variables should have descriptive names. For instance, `count` is not descriptive: half of all integers are used for counting. Count of what?
- Do not use global variables:

  ```cpp
  int i;
  int main() {
    cin >> i;
  }
  ```
3.4.3 Conditionals

3.4.4 Looping

The loop variable should be declared locally, in the loop header, if there is no overwhelming reason for declaring it global.

Local declaration:

```cpp
for ( int i=0; i<N; i++) {
    // something with i
}
```

global:

```cpp
int i;
for ( i=0; i<N; i++) {
    // something with i
    if (something) break;
}
```

// look at i to see where the break was

Use range-based loops if the index is not strictly needed.

3.4.5 Functions

There is no preference whether to declare a function entirely before the main, or after the main with only its prototype before.

Defined before:

```cpp
bool f( double x ) {
    return x>0;
}

int main() {
    cout << f(5.1);
}
```

Only proto given before:

```cpp
bool f(double x);
int main() {
    cout << f(5.1);
}
```

```cpp
bool f( double x ) {
    return x>0;
}
```

Only use C++-style parameter passing by value or reference: not C-style `int` parameters and such.

3.4.6 Scope

Variables should be declared in the most local scope that uses them. Declaring all variables at the start of a subprogram is needed in Fortran, but is to be discouraged in C++

3.4.7 Structures

Do not declare a single global structure:

Good:

```cpp
struct Point { double x,y; };
int main() {
    Point mypoint;
    cin >> mypoint.x;
}
```

Not good:

```cpp
struct Point { double x,y; } mypoint;
int main() {
    cin >> mypoint.x;
}
```
3. Teachers guide

3.4.8 Classes

- Do not declare data members public. Write accessor functions, but only if needed.
- Only write accessor functions if they are really needed.
- Make sure method names are descriptive of what the method does.
- The keyword this is hardly ever needed. This usually means the student has been looking at stackoverflow too much.

3.4.9 Arrays and vectors

- Do not use old-style C arrays.
  ```
  int indexes[5];
  ```
- Certainly never use malloc or new.
- Iterator operations (begin, erase) are seldom needed.

3.4.10 Strings

Do not use old-style C strings:
```
char *words = "and another thing";
```

3.4.11 Other remarks

3.4.11.1 Uninitialized variables

Uninitialized variables can lead to undefined or indeterminate behavior. Bugs, in other words.
```
int i_solution;
int j_solution;
bool found_solution;
for(int i = 0; i < 10; i++){
  for(int j = 0; j < 10; j++){
    if(i*j > n){
      i_solution = i;
      j_solution = j;
      found_solution = true;
      break;
    }
  }
  if(found_solution){break;}
}
cout << i_solution << "," << j_solution << endl;
```

```%
icpc -o missinginit missinginit.cxx && echo 40 | ./missinginit
0, -917009232
6, 7
``` 

This whole issue can be sidestepped if the compiler or runtime system can detect this issue. Code structure will often prevent detection, but runtime detection is always possible, in principle.

For example, the Intel compiler can install a run-time check:
3.4. Grading guide

```bash
% icpc -check=uninit -o missinginit missinginit.cxx && echo 40 | ./missinginit
```

Run-Time Check Failure: The variable 'found_solution' is being used in missinginit.cxx(22,5) without being initialized.

Aborted (core dumped)

3.4.11.2 Clearing objects and arrays

The following idiom is found regularly:

```cpp
vector<int> testvector;
for ( /* possibilities */ ) {
    testvector.push_back( something );
    if ( testvector.sometest() )
        // remember this as the best
    testvector.clear();
}
```

A similar idiom occurs with classes, which students endow with a `reset()` method.

This is more elegantly done by declaring the testvector inside the loop: the reset is then automatically taken care of.

The general principle here is that entities need to be declared as local as possible.
PART II

C++
Chapter 4

Basic elements of C++

4.1 From the ground up: Compiling C++

In this chapter and the next you are going to learn the C++ language. But first we need some externalia: how do you deal with any program?

Two kinds of files

In programming you have two kinds of files:

- **source files**, which are understandable to you, and which you create with an editor such as vi or emacs; and
- **binary files**, which are understandable to the computer, and unreadable to you.

Your source files are translated to binary by a **compiler**, which ‘compiles’ your source file.

Let’s look at an example:

```
icpc -o myprogram myprogram.cxx
```

This means:

- you have a source code file `myprogram.cxx`;
- and you want an executable file as output called `myprogram`,
- and your compiler is the Intel compiler `icpc`. (If you want to use the C++ compiler of the GNU project you specify `g++`.)

Let’s do an example.

Exercise 4.1. Make a file `zero.cc` with the following lines:

```cpp
#include <iostream>
using std::cout;
using std::endl;

int main() {
    return 0;
}
```

and compile it. Intel compiler:

```
icpc -o zeroprogram zero.cc
```
4. Basic elements of C++

Run this program (it gives no output):

```
./zeroprogram
```

**Compile line**

- icpc: compiler. Alternative: use g++ or clang++
- -o zeroprogram: output into a binary name of your choosing
- zero.cc: your source file.

In the above program:
1. The first three lines are magic, for now. Always include them.
2. The `main` line indicates where the program starts; between its opening and closing brace will be the program statements.
3. The `return` statement indicates successful completion of your program.

As you may have guessed, this program produces absolutely no output when you run it.

**Exercise 4.2.** Add this line:

```
cout << "Hello world!" << endl;
```

(copied from the pdf file is dangerous! please type it yourself)

Compile and run again.

(Did you indent the ‘hello world’ line? Did your editor help you with the indentation?)

**File names**

File names can have extensions: the part after the dot.

- **program.cxx** or **program.cc** are typical extensions for C++ sources.
- **program.cpp** is also used, but there is a possible confusion with ‘C PreProcessor’.
- Using **program** without extension usually indicates an **executable**.

**Review 4.3.** True or false?

1. The programmer only writes source files, no binaries.
2. The computer only executes binary files, no human-readable files.

### 4.1.1 A quick word about unix commands

The compile line

```
g++ -o myprogram myprogram.cxx
```

can be thought of as consisting of three parts:

- The command `g++` that starts the line and determines what is going to happen;
- The argument `myprogram.cxx` that ends the line is the main thing that the command works on; and

**Introduction to Scientific Programming**
• The option/value pair \(-o\ myprogram\). Most Unix commands have various options that are, as the name indicates, optional. For instance you can tell the compiler to try very hard to make a fast program:

\[
\text{g++ -O3 -o myprogram myprogram.cxx}
\]

Options can appear in any order, so this last command is equivalent to

\[
\text{g++ -o myprogram -O3 myprogram.cxx}
\]

Be careful not to mix up argument and option. If you type

\[
\text{g++ -o myprogram.cxx myprogram}
\]

then Unix will reason: ‘myprogram.cxx is the output, so if that file already exists (which, yes, it does) let’s just empty it before we do anything else’. And you have just lost your program. Good thing that editors like \(\text{emacs}\) keep a backup copy of your file.

### 4.1.2 C++ is a moving target

The C++ language has gone through a number of standards. (This is described in some detail in section 26.7.) In this course we focus on a fairly recent standard: C++17. Unfortunately, your compiler will assume an earlier standard, so constructs taught here may be marked as ungrammatical.

You can tell your compiler to use the modern standard:

\[
\text{icpc -std=c++17 [other options]}
\]

but to save yourself a lot of typing, you can define

\[
\text{alias icpc='icpc -std=c++17'}
\]

in your shell startup files. On the class \(\text{isp}\) machine this alias has been defined by default.

### 4.2 Statements

Each programming language has its own (very precise!) rules for what can go in a source file. Globally we can say that a program contains instructions for the computer to execute, and these instructions take the form of a bunch of ‘statements’. Here are some of the rules on statements; you will learn them in more detail as you go through this book.

**Program statements**

- A program contains statements, each terminated by a semicolon.
- ‘Curly braces’ can enclose multiple statements.
- A statement can correspond to some action when the program is executed.
- Some statements are definitions, of data or of possible actions.
- Comments are ‘Note to self’, short:

\[
\text{cout} \ll \text{"Hello world"} \ll \text{endl}; // \text{say hi!}
\]

and arbitrary:
4. Basic elements of C++

```cpp
cout << /* we are now going 
to say hello 
*/ "Hello!" << /* with newline: */ endl;
```

Exercise 4.4. Take the ‘hello world’ program you wrote above, and duplicate the hello-line. Compile and run.

Does it make a difference whether you have the two hellos on the same line or on different lines?

Experiment with other changes to the layout of your source. Find at least one change that leads to a compiler error. Can you relate the message to the error?

Errors

There are two types of errors that your program can have:

1. **Syntax or compile-time errors**: these arise if what you write is not according to the language specification. The compiler catches these errors, and it refuses to produce a binary file.
2. **Run-time errors**: these arise if your code is syntactically correct, and the compiler has produced an executable, but the program does not behave the way you intended or foresaw. Examples are divide-by-zero or indexing outside the bounds of an array.

Review 4.5. True or false?

- If your program compiles correctly, it is correct.
- If you run your program and you get the right output, it is correct.

Fixed elements

You see that certain parts of your program are inviolable:

- There are **keywords** such as `return` or `cout`; you cannot change their definition.
- Curly braces and parentheses need to be matched.
- There has to be a `main` keyword.
- The `iostream` and `std` are usually needed.

A word about `using`. After

```cpp
#include <iostream>
```

you can write `std::cout` in your program, but the ‘using’ statements allow you to just write `cout`.

Exercise 4.6. Experiment with the `cout` statement. Replace the string by a number or a mathematical expression. Can you guess how to print more than one thing, for instance:

- the string `One third is, and`
- the result of the computation `1/3`,

with the same `cout` statement?

Return statement

- The language standard says that `main` has to be of type `int`; the `return statement` returns an int.
4.3. Variables

A program could not do much without storing data: input data, temporary data for intermediate results, and final results. Data is stored in variables, which have

- a name, so that you can refer to them,
- a datatype, and
- a value.

Think of a variable as a labeled placed in memory.

- The variable is defined in a variable declaration,
- which can include an variable initialization.
- After a variable is defined, and given a value, it can be used,
- or given a (new) value in a variable assignment.

**Typical variable lifetime**

```c
int i,j; // declaration
i = 5; // set a value
i = 6; // set a new value
j = i+1; // use the value of i
i = 8; // change the value of i
    // but this doesn’t affect j:
    // it is still 7.
```

4.3.1 Variable declarations

A variable is defined once in a variable declaration, but it can be given a (new) value multiple times. It is not an error to use a variable that has not been given a value, but it may lead to strange behaviour at runtime, since the variable may contain random memory contents.

**Variable names**

- A variable name has to start with a letter;
- a name can contains letters and digits, but not most special characters, except for the underscore.
- For letters it matters whether you use upper or lowercase: the language is case sensitive.
- Words such as `main` or `return` are reserved words.
- Usually `i` and `j` are not the best variable names: use `row` and `column`, or other meaningful
names, instead.

**Declaration**

There are a couple of ways to make the connection between a name and a type. Here is a simple *variable declaration*, which establishes the name and the type:

```cpp
int n;
float x;
int n1, n2;
double re_part, im_part;
```

**Where do declarations go?**

Declarations can go pretty much anywhere in your program, but they need to come before the first use of the variable.

Note: it is legal to define a variable before the main program but that’s not a good idea. Please only declare *inside* main (or inside a function et cetera).

**Review 4.7.** Which of the following are legal variable names?

1. mainprogram
2. main
3. Main
4. 1forall
5. one4all
6. one_for_all
7. onefor{all}

**4.3.2 Assignments**

Setting a variable

```cpp
i = 5;
```

means storing a value in the memory location. It is not the same as defining a mathematical equality

```cpp
let i = 5.
```

**Assignment**

Once you have declared a variable, you need to establish a value. This is done in an *assignment* statement. After the above declarations, the following are legitimate assignments:

```cpp
n = 3;
x = 1.5;
n1 = 7; n2 = n1 * 3;
```

These are not math equations: variable on the lhs gets the value of the rhs.

You see that you can assign both a simple value or an *expression*.
Special forms

Update:

\[
\begin{align*}
x &= x+2; \\
y &= y/3; \\
&// can be written as \\
x &=+ 2; \\
y &= 3;
\end{align*}
\]

Integer add/subtract one:

\[
i++; \\
j--; /* same as: */ \\
i+=1; \\
j-=1;
\]

Exercise 4.8. Which of the following are legal? If they are, what is their meaning?

1. \( n = n; \)
2. \( n = 2n; \)
3. \( n = n2; \)
4. \( n = 2k; \)
5. \( n/2 = k; \)
6. \( n /= k; \)

Exercise 4.9.

```cpp
#include <iostream>
using std::cout;
using std::endl;
int main() {
    int i;
    int j = i+1;
    cout << j << endl;
    return 0;
}
```

What happens?

1. Compiler error
2. Output: 1
3. Output is undefined
4. Error message during running the program.

4.3.3 Terminal input

In most of your program, variables will be assigned values that arise somewhere in the course of the computation. However, especially in the start of your program, you may want to have some values that are specified interactively, by you typing them in.

**Terminal input**

To make a program run dynamic, you can set starting values from keyboard input. For this, use `cin`, which takes keyboard input and puts it in a numerical (or string) variable.
4. Basic elements of C++

```cpp
// add at the top of your program:
using std::cin;

// then in your main:
int i;
cin >> i;
```

## 4.3.4 Datatypes

### Datatypes

Variables come in different types:
- We call a variable of type `int`, `float`, `double` a numerical variable.
- Complex numbers will be discussed later.
- For characters: `char`. Strings are complicated; see later.
- Truth values: `bool`
- You can make your own types. Later.

For complex numbers see section 24.1. For strings see chapter 12.

At some point you may start to wonder precisely what the range of integers or real numbers is that is stored in an `int` or `float` variable. This is addressed in section 24.6.

### 4.3.4.1 Integers

Mathematically, integers are a special case of real numbers. In a computer, integers are stored very differently from real numbers – or technically, floating point numbers.

C++ integers are stored as binary number and a sign bit, though not as naively as this sounds. The upshot is that normally within a certain range all integer values can be represented.

**Exercise 4.10.** These days, the default amount of storage for an `int` is 32 bits. After one bit is used for the sign, that leave 31 bits for the digits. What is the representible integer range?

The integer type in C++ is `int`:

```cpp
int my_integer;
my_integer = 5;
cout << my_integer << endl;
```

There are also `short` and `long` integers.
- A short int is at least 16 bits;
- An integer is at least 16 bits, but often 32 bits;
- A long integer is at least 32 bits, but often 64;
- A `long long` integer is at least 64 bits.

For the whole truth of these so-called data models, see [https://en.cppreference.com/w/cpp/language/types](https://en.cppreference.com/w/cpp/language/types).
4.3. Variables

4.3.4.2 Floating point variables

Floating point number is the computer science-y name for scientific notation: a number written like

\[ +6 \cdot 022 \times 10^{23} \]

with:

- an optional sign;
- an integral part;
- a decimal point, or more generally radix point in other number bases;
- a fractional part, also known as mantissa or significand;
- and an exponent part: base to some power.

Floating point numbers are also referred to as ‘real numbers’ (in fact, in the Fortran language they are defined with the keyword `Real`), but this is sloppy working. Since only a finite number of bits/digits is available, only terminating fractions are representable. For instance, since computer numbers are binary, 1/2 is representable but 1/3 is not.

Exercise 4.11. Can you think of a way that non-terminating fractions, including such numbers such as \( \sqrt{2} \), are still representable?

- You can assign variables of one type to another, but this may lead to truncation (assigning a floating point number to an integer) or unexpected bits (assigning a single precision floating point number do a double precision).

Floating points numbers do not behave like mathematical numbers.

**Warning: floating point arithmetic**

Floating point arithmetic is full of pitfalls.

- Don’t count on \( 3 \times (1. / 3) \) being exactly 1.
- Not even associative.

(See Eijkhout, Introduction to High Performance Computing, chapter 3.)

The following exercise illustrates another point about computer numbers.

Exercise 4.12. Define

\[
\| \text{float one} = 1.; \|
\]

and

1. Read a float \( \text{eps} \).
2. Make a new variable that has the value \( \text{one + eps} \). Print this.
3. Make another variable that is the previous one minus \( \text{one} \). Print the result again.
4. Test your program with \( .001, .0001, .00001, .000001 \). Do you understand the result?

Complex numbers exist, see section 24.1.
4. Basic elements of C++

4.3.4.3 Boolean values

Truth values

So far you have seen integer and real variables. There are also boolean values which represent truth values. There are only two values: true and false.

```c++
bool found(false);
found = true;
```

4.3.4.4 Strings

Strings, that is, strings of characters, are not a C++ built-in datatype. Thus, they take some extra setup to use. See chapter 12 for a full discussion. For now, if you want to use strings:

Quick intro to strings

- Add the following at the top of your file:

```c++
#include <string>
using std::string;
```
- Declare string variables as

```c++
string name;
```
- And you can now `cin` and `cout` them.

Exercise 4.13. Write a program that asks for the user’s first name, uses `cin` to read that, and prints something like Hello, Susan! in response.

What happens if you enter first and last name?

4.3.5 Complex numbers

See section 24.1.

4.3.6 Initialization

It is possible to give a variable a value right when it’s created. This is known as initialization and it’s different from creating the variable and later assigning to it (section 4.3.2).

Initialization syntax

There are two ways of initializing a variable

```c++
int i = 5;
int j{6};
```

Note that writing

```c++
int i;
i = 7;
```
is not an initialization: it’s a declaration followed by an assignment.

If you declare a variable but not initialize, you can not count on its value being anything, in particular not zero. Such implicit initialization is often omitted for performance reasons.

### 4.4 Input/Output, or I/O as we say

A program typically produces output. For now we will only display output on the screen, but output to file is possible too. Regarding input, sometimes a program has all information for its computations, but it is also possible to base the computation on user input.

#### Terminal output

You have already seen **cout**:

```c++
float x = 5;
cout << "Here is the root: " << sqrt(x) << endl;
```

#### Terminal input

**cin** is limited. There is also **getline**, which is more general.

For fine-grained control over the output, and file I/O, see chapter 13.

### 4.5 Expressions

The most basic step in computing is to form expressions such as sums, products, logical conjunctions, string appending. Let’s start with constants.

#### 4.5.1 Numbers

##### 4.5.1.1 Integers

Integers consist of a sequence of digits, preceeded by a plus or minus sign.

Hexadecimal integers start with `0x` or `0X`.

Binary numbers start with `0b`.

##### 4.5.1.2 Floating point numbers

Floating point numbers are by default **double**: double precision.

```
1.5 1.5e+5
```

Use a suffix `1.5f` for **float**: single precision.

```
1.5f 1.5e+5f
```

Use a suffix `1.5L` for **long double**: quadruple precision.

```
1.5L 1.5e+5L
```

Hexadecimal floating points numbers have a complicated format.
4. Basic elements of C++

4.5.2 Numerical expressions

Expressions in programming languages for the most part look the way you would expect them to.

- Mathematical operators: +, -, /, and * for multiplication.
- Integer modulus: 5 % 2
- You can use parentheses: 5 * (x + y). Use parentheses if you’re not sure about the precedence rules for operators.
- C++ does not have a power operator (Fortran does): ‘Power’ and various mathematical functions are realized through library calls.

Math library calls

```cpp
#include <cmath>

x = pow(3, .5);
```

For squaring, usually better to write `x * x` than `pow(x, 2)`.

Exercise 4.14. Write a program that:

- displays the message *Type a number*,
- accepts an integer number from you (use `cin`),
- makes another variable that is three times that integer plus one,
- and then prints out the second variable.

4.5.3 Truth values

In addition to numerical types, there are truth values, `true` and `false`, with all the usual logical operators defined on them.

Boolean expressions

- Relational operators: ==, !=, <, <=, >, >=
- Boolean operators: `not, and, or` (oldstyle: `! && ||`);
- Shortcut operators:

  ```cpp
  if ( x>=0 && sqrt(x)<5 ) {} 
  ```

4.5.3.1 Short-cut operators

Logical expressions in C++ are evaluated using shortcut operators. Strictly speaking, the expression

```cpp
x>=0 && sqrt(x)<2
```

would be a problem for negative `x` values, because you have to evaluate both members.

However, C++ has a strict left-to-right evaluation of expressions. If `x` is negative, the ‘and’ conjunction can already be concluded to be false, and so the second part will never be evaluated. Similarly, ‘or’ conjunctions will only be evaluated until the first true clause.
4.5.3.2 Bit operators

The ‘true’ and ‘false’ constants could strictly speaking be stored in a single bit. C++ does not do that, but there are bit operators that you can apply to, for instance, all the bits in an integer.

Bit operators

Bitwise: & | ^

4.5.4 Type conversions

Since a variable has one type, and will always be of that type, you may wonder what happens with

\[
\text{float } x = 1.5; \\
\text{int } i; \\
\text{i = x;}
\]

or

\[
\text{int } i = 6; \\
\text{float } x; \\
x = i;
\]

• Assigning a floating point value to an integer truncates the latter.
• Assigning an integer to a floating point variable fills it up with zeros after the decimal point.

Exercise 4.15.

• What happens when you assign a positive floating point value to an integer variable?
• What happens when you assign a negative floating point value to an integer variable?
• What happens when you assign a float to a double? Try various numbers for the original float. Can you explain the result? (Hint: think about the conversion between binary and decimal.)

The rules for type conversion in expressions are not entirely logical. Consider

\[
\text{float } x; \text{ int } \text{i=5, j=2}; \\
x = i/j;
\]

This will give 2 and not 2.5, because \(i/j\) is an integer expression and is therefore completely evaluated as such, giving 2 after truncation. The fact that it is ultimately assigned to a floating point variable does not cause it to be evaluated as a computation on floats.

You can force the expression to be computed in floating point numbers by writing

\[
x = (1.*i)/j;
\]

or any other mechanism that forces a conversion, without changing the result. Another mechanism is the cast; this will be discussed in section 26.3.

Exercise 4.16. Write a program that asks for two integer numbers \(n1, n2\).

• Assign the integer ratio \(n1/n2\) to an integer variable.
4. Basic elements of C++

- Can you use this variable to compute the modulus

\[ n_1 \mod n_2 \]

(without using the \% modulus operator!)
Print out the value you get.
- Also print out the result from using the modulus operator: \%.
- Investigate the behaviour of your program for negative inputs. Do you get what you were expecting?

Exercise 4.17. Write two programs, one that reads a temperature in Centigrade and converts to Fahrenheit, and one that does the opposite conversion.

\[ C = (F - 32) \cdot \frac{5}{9}, \quad F = \frac{9}{5} C + 32 \]

Check your program for the freezing and boiling point of water.
(Do you know the temperature where Celsius and Fahrenheit are the same?)
Can you use Unix pipes to make one accept the output of the other?

Review 4.18. True of false?
1. Within a certain range, all integers are available as values of an integer variable.
2. Within a certain range, all real numbers are available as values of a float variable.
3. \[ 5(7+2) \] is equivalent to 45.
4. \( 1--1 \) is equivalent to zero.
5. \texttt{int i = 5/3.;} The variable \texttt{i} is 2.
6. \texttt{float x = 2/3;} The variable \texttt{x} is approximately 0.6667.

4.6 Advanced topics

4.6.1 Library functions

Some functions, such as \texttt{abs} can be included through \texttt{cmath}:

\[
\begin{align*}
\#include & \text{ <cmath> } \\
& \text{ using std::abs; }
\end{align*}
\]

Others, such as \texttt{max}, are in the less common \texttt{algorithm}:

\[
\begin{align*}
\#include & \text{ <algorithm> } \\
& \text{ using std::max; }
\end{align*}
\]

4.6.2 Number values and undefined values

A computer allocates a fixed amount of space for integers and floating point numbers, typically 4 or 8 bytes. That means that not all numbers are representable.
4.6. Advanced topics

- Using 4 bytes, that is 32 bits, we can represent $2^{32}$ integers. Typically this is the range $-2^{31} \ldots 0 \ldots 2^{31} - 1$.

- Floating point numbers are represented by a sign bit, an exponent, and a number of significant digits. For 4-byte numbers, the number of significant (decimal) digits is around 6; for 8-byte numbers it is around 15.

If you compute a number that ‘fall in between the gaps’ of the representable numbers, it gets truncated or rounded. The effects of this on your computation constitute its own field of numerical mathematics, called *roundoff error analysis*.

If a number goes outside the bounds of what is representable, it becomes either:

- \( \text{Inf} \): infinity. This happens if you add or multiply enough large numbers together. There is of course also a value \(-\text{Inf}\). Or:
- \( \text{NaN} \): not a number. This happens if you subtract one \( \text{Inf} \) from another, or do things such as taking the root of a negative number.

Your program will not be interrupted if a \( \text{NaN} \) or \( \text{Inf} \) is generated: the computation will merrily (and at full speed) progress with these numbers. See section 24.6 for detection of such quantities.

Some people advocate filling uninitialized memory with such illegal values, to make it recognizable as such.

### 4.6.3 Constants

#### Floating point constants

- Default: \texttt{double}
- Float: \texttt{3.14f} or \texttt{3.14F}
- Long double: \texttt{1.22l} or \texttt{1.22L}

#### Integer constants

Integers are normally written in decimal, and stored in 32 bits. If you need something else:

```c
int d = 42;
int o = 052; // start with zero
int x = 0x2a;
int X = 0X2A;
int b = 0b101010;
long ell = 42L;
```

Binary numbers are new to C++17.

### 4.6.4 Numerical precision

Truncation and precision are tricky things.
4. Basic elements of C++

```cpp
Code:
double point3d = .3/.7;
float
point3f = .3f/.7f,
point3t = point3d;
cout << "double precision: "
  << point3d << endl
<< "single precision: "
  << point3f << endl
<< "difference with truncation:"
  << point3t - point3f
  << endl;
```

Output
[basic] point3:
double precision: 0.428571
single precision: 0.428571
difference with truncation:-2.98023e-08

4.7 Review questions

Review 4.19. What is the output of:
```cpp
int m=32, n=17;
cout << n%m << endl;
```

Review 4.20. Given
```cpp
int n;
```
give an expression that uses elementary mathematical operators to compute n-cubed: \( n^3 \). Do you get the correct result for all \( n \)? Explain.

How many elementary operations does the computer perform to compute this result?

Can you now compute \( n^6 \), minimizing the number of operations the computer performs?
Chapter 5

Conditionals

A program consisting of just a list of assignment and expressions would not be terribly versatile. At least you want to be able to say ‘if \( x > 0 \), do one computation, otherwise compute something else’, or ‘until some test is true, iterate the following computations’. The mechanism for testing and choosing an action accordingly is called a *conditional*.

5.1 Conditionals

Here are some forms a conditional can take.

A single statement, executed if the test is true:

\[
\text{if} \ (x < 0) \\
\quad x = -x;
\]

Single statement in the true branch, and likewise a single statement in the false branch:

\[
\begin{align*}
\text{if} \ (x \geq 0) \\
\quad x = 1; \\
\text{else} \\
\quad x = -1;
\end{align*}
\]

Both in the true and the false branch multiple statements are allowed, if you enclose them in curly braces:

\[
\begin{align*}
\text{if} \ (x < 0) \ { \\
\quad x = 2 \times x; \ y = y/2; \\
\} \text{ else } \{ \\
\quad x = 3 \times x; \ y = y/3; \\
\}
\end{align*}
\]

You can chain conditionals by extending the *else* part. In this example the dots stand for omitted code:

\[
\begin{align*}
\text{if} \ (x > 0) \ { \\
\quad \ldots \ldots \\
\} \text{ else if} \ (x < 0) \ { \\
\quad \ldots \ldots \\
\} \text{ else} \ { \\
\quad \ldots \ldots \\
\}
\end{align*}
\]

Conditionals can also be nested:
5. Conditionals

```c
if (x>0) {
    if (y>0) {
        ....
    } else {
        ....
    }
} else {
    ....
}
```

- In that last example the outer curly brackets in the true branch are optional. But it’s safer to use them anyway.
- When you start nesting constructs, use indentation to make it clear which line is at which level. A good editor helps you with that.

Exercise 5.1. For what values of \( x \) will the left code print ‘b’?

For what values of \( x \) will the right code print ‘b’?

```c
float x = /* something */
if (x > 1) {
    cout << "a" << endl;
    if (x > 2) {
        cout << "b" << endl;
    }
}
```

```c
float x = /* something */
if (x > 1) {
    cout << "a" << endl;
} else if (x > 2) {
    cout << "b" << endl;
}
```

5.2 Operators

You have already seen arithmetic expressions; now we need to look at logical expressions: just what can be tested in a conditional. Here is a fragment of language grammar that spells out what is legal. You see that most of the rules are recursive, but there is an important exception.

What are logical expressions?

```c
logical_expression ::
    comparison_expression
    | NOT comparison_expression
    | logical_expression CONJUNCTION comparison_expression

comparison_expression ::
    numerical_expression COMPARE numerical_expression

numerical_expression ::
    quantity
    | numerical_expression OPERATOR quantity

quantity :: number | variable
```

Comparison and logical operators

Here are the most common logic operators and comparison operators.
### 5.2. Operators

<table>
<thead>
<tr>
<th>Operator</th>
<th>meaning</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>equals</td>
<td>x==y-1</td>
</tr>
<tr>
<td>!=</td>
<td>not equals</td>
<td>x+x!=5</td>
</tr>
<tr>
<td>&gt;</td>
<td>greater</td>
<td>y&gt;x-1</td>
</tr>
<tr>
<td>&gt;=</td>
<td>greater or equal</td>
<td>sqrt(y)&gt;7</td>
</tr>
<tr>
<td>&lt;</td>
<td>less, less equal</td>
<td>x&lt;1 &amp;&amp; x&gt;0</td>
</tr>
<tr>
<td>&lt;=</td>
<td>and, or</td>
<td>x&lt;1 and x&gt;0</td>
</tr>
<tr>
<td>!</td>
<td>not</td>
<td>!( x&gt;1 &amp;&amp; x&lt;2 )</td>
</tr>
<tr>
<td>&amp;&amp;</td>
<td>and</td>
<td>x&lt;1 and x&gt;0</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Remark 1** There are also bitwise operators.

**Code:**
```c++
int x=6,y=3;
cout << "6|3 = " << (x|y) << endl;
cout << "6&3 = " << (x&y) << endl;
```

**Output**

<table>
<thead>
<tr>
<th>bitor:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>3 = 7</td>
</tr>
<tr>
<td>6&amp;3 = 2</td>
<td></td>
</tr>
</tbody>
</table>

**Exercise 5.2.** The following code claims to detect if an integer has more than 2 digits.

**Code:**
```c++
int i;
cin >> i;
if ( i>100 )
    cout << "That number " << i << " had more than 2 digits" << endl;
```

**Output**

<table>
<thead>
<tr>
<th>if:</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>... with 50 as input ....</td>
<td></td>
</tr>
<tr>
<td>... with 150 as input ....</td>
<td></td>
</tr>
<tr>
<td>That number 150 had more than 2 digits</td>
<td></td>
</tr>
</tbody>
</table>

Fix the small error in this code. Also add an ‘else’ part that prints if a number is negative.

You can base this off the file *if.cxx*.

**Exercise 5.3.** Read in an integer. If it is even, print ‘even’, otherwise print ‘odd’:

```c++
if ( /* your test here */ )
    cout << "even" << endl;
else
    cout << "odd" << endl;
```

Then, rewrite your test so that the true branch corresponds to the odd case.

In exercise 5.3 it didn’t matter whether you used the test for even or for odd, but sometimes it does make a difference how you arrange complicated conditionals. In the following exercise, think about how to arrange the tests. There is more than one way.
Exercise 5.4. Read in a positive integer. If it’s a multiple of three print ‘Fizz!’; if it’s a multiple of five print ‘Buzz!’. It it is a multiple of both three and five print ‘Fizzbuzz!’. Otherwise print nothing.

Note:
- Capitalization.
- Exclamation mark.
- Your program should display at most one line of output.

Review 5.5. True or false?
- The tests `if (i>0)` and `if (0<i)` are equivalent.
- The test
  ```
  if (i<0 && i>1)
  cout << "foo"
  ```
  prints `foo` if `i < 0` and also if `i > 1`.
- The test
  ```
  if (0<i<1)
  cout << "foo"
  ```
  prints `foo` if `i` is between zero and one.

Review 5.6. Any comments on the following?
```
bool x;
// ... code with x ...
if ( x == true )
// do something
```

5.3 Switch statement

If you have a number of cases corresponding to specific integer values, there is the `switch` statement.

Switch statement example

Cases are executed consecutively until you ‘break’ out of the switch statement:
5.4 Scopes

The true and false branch of a conditional can consist of a single statement, or of a block in curly brackets. Such a block creates a scope where you can define local variables.

```
if (something) {
    int i;
    .... do something with i
}
// the variable 'i' has gone away.
```

See chapter 8 for more detail.

5.5 Advanced topics

5.5.1 Short-circuit evaluation

C++ logic operators have a feature called short circuit evaluation: a logical operator stops evaluating when the result is clear. For instance, in

```
clause1 and clause2
```

the second clause is not evaluated if the first one is false, because the truth value of this conjunction is already determined.

Likewise, in

```
clause1 or clause2
```
5. Conditionals

the second clause is not evaluated if the first one is true.

This mechanism allows you to write

\[
\text{if ( } x>0 \text{ and } \sqrt{x} < 10 \text{ ) } \{ \text{/* ... */ } \}
\]

Without short-circuit evaluation the square root operator could be applied to negative numbers.

5.5.2 Ternary if

The true and false branch of a conditional contain whole statements. For example

\[
\text{if (foo) }\quad x = 5; \\
\text{else} \quad y = 6;
\]

But what about the case where the true and false branch perform in effect the same action, and only differ by an expression?

\[
\text{if (foo) }\quad x = 5; \\
\text{else} \quad x = 6;
\]

For this case there is the ternary if, which acts as if it’s an expression itself, but chosen between two expressions. The previous assignment to \(x\) then becomes:

\[
x = \text{foo} ? 5 : 6;
\]

Surprisingly, this expression can even be in the left-hand side:

\[
\text{foo} \text{? x : y} = 7;
\]

5.5.3 Initializer

The C++17 introduced a new form of the if and switch statement: it is possible to have a single statement of declaration prior to the test. This is called the initializer.

This is particularly elegant if the init statement is a declaration, because the declared variable is then local to the conditional. Previously one would have had to write

\[
\text{char } c; \\
\text{c = getchar();} \\
\text{if ( c!='a' )} \text{ /* ... */}
\]

with the variable globally defined.
5.6 Review questions

Review 5.8. T/F: the following is a legal program:

```cpp
#include <iostream>
int main() {
    if (true)
        int i = 1;
    else
        int i = 2;
    std::cout << i;
    return 0;
}
```

Review 5.9. T/F: the following are equivalent:

```cpp
if (cond1)
    i = 1;
else if (cond2)
    i = 2;
else
    i = 3;
```

compare:

```cpp
if (cond1)
    i = 1;
else {
    if (cond2)
        i = 2;
    else
        i = 3;
```
5. Conditionals
Chapter 6

Looping

There are many cases where you want to repeat an operation or series of operations:

- A time-dependent numerical simulation executes a fixed number of steps, or until some stopping test.
- Recurrences:
  \[ x_{i+1} = f(x_i) \]
- Inspect or change every element of a database table.

The C++ construct for such repetitions is known as a loop: a number of statements that get repeated. The two types of loop statement in C++ are:

- the for loop which is typically associated with a pre-determined number of repetitions, and with the repeated statements being based on a counter of some sort; and
- the while loop, where the statements are repeated indefinitely until some condition is satisfied.

However, the difference between the two is not clear-cut: in many cases you can use either.

We will now first consider the for loop; the while loop comes in section 6.2.

6.1 The ‘for’ loop

In the most common case, a for loop has a loop counter, ranging from some lower to some upper bound. An example showing the syntax for this simple case is:

```cpp
int sum_of_squares(0);
for (int var=low; var<upper; var++) {
    sum_of_squares += var*var;
}
cout << "The sum of squares from " << low << " to " << upper << " is " << sum_of_squares << endl;
```

The for line is called the loop header, and the statements between curly brackets the loop body. Each execution of the loop body is called an iteration.

‘For’ statement

Sometimes you need to repeat a statement a number of times. That’s where the loop comes in. A loop has a counter, called a loop variable, which (usually) ranges from a lower bound to an upper bound.
Here is the syntax in the simplest case:

```cpp
int sum_of_squares = 0;
for (int var = low; var < upper; var++) {
    sum_of_squares += var * var;
}
cout << "The sum of squares from "
    << low << " to " << upper
    << " is " << sum_of_squares << endl;
```

**Loop syntax: variable**

The loop variable is usually an integer:

```cpp
for (int index = 0; index < max_index; index++) {
    ...
}
```

But other types are allowed too:

```cpp
for (float x = 0.0; x < 10.0; x += delta) {
    ...
}
```

Beware the stopping test!

**Loop syntax: test**

- If this test is true, do the next iteration.
- Done before the first iteration too!
- Test can be empty. What does this mean?

```cpp
for (int i = 0; ; i++) {...}
for (int i = 0; i < N; i++) {...}
```

**Loop syntax: increment**

Increment performed after each iteration. Most common:

- `i++` for a loop that counts forward;
- `i--` for a loop that counts backward;

Others:

- `i+=2` to cover only odd or even numbers, depending on where you started;
- `i+=10` to cover powers of ten.

Even optional:

```cpp
for (int i = 0; i < N; ) {
    // stuff
    if (something) i += 1; else i += 2;
}
```

**Exercise 6.1.** Take the code of slide 6.1 and modify it to sum only the squares of every other number, starting at `low`.

Can you find a way to sum the squares of the even numbers $\geq low$?
6.1. The ‘for’ loop

*C difference:* Declaring the loop variable in the loop header is also a modern addition to the C language. Use compiler flag `-std=c99`.

If you want to perform $N$ iterations you can write

```
for (int iter=0; iter<N; iter++)
```

or

```
for (int iter=1; iter<=N; iter++)
```

The former is slightly more idiomatic to C++.

The loop header has three components, all of which are optional.

- An initialization. This is usually a declaration and initialization of an integer loop variable. Using floating point values is less advisable.
- A stopping test, usually involving the loop variable. If you leave this out, you need a different mechanism for stopping the loop; see section 6.2.
- An increment, often $i++$ or spelled out $i=i+1$. You can let the loop count down by using $i--$.

**Exercise 6.2.** Read an integer value with `cin`, and print ‘Hello world’ that many times.

**Exercise 6.3.** Extend exercise 6.2: the input 17 should now give lines

```
Hello world 1
Hello world 2
....
Hello world 17
```

Can you do this both with the loop index starting at 0 and 1? Also, let the numbers count down. What are the starting and final value of the loop variable and what is the update? There are several possibilities!

This is how a loop is executed.

- The initialization is performed.
- At the start of each iteration, including the very first, the stopping test is performed. If the test is true, the iteration is performed with the current value of the loop variable(s).
- At the end of each iteration, the increment is performed.

**Review 6.4.** For each of the following loop headers, how many times is the body executed? (You can assume that the body does not change the loop variable.)

- `for (int i=0; i<7; i++)`
- `for (int i=0; i<=7; i++)`
- `for (int i=0; i<0; i++)`
6. Looping

Review 6.5. What is the last iteration executed?

\[
\text{for (int } i=1; i\leq 2; i=i+2)\\
\text{for (int } i=1; i\leq 5; i*=2)\\
\text{for (int } i=0; i<0; i--)\\
\text{for (int } i=5; i\geq 0; i--)\\
\text{for (int } i=5; i>0; i--)\\
\]

Some variations on the simple case.

**Loop variable declaration**  It is preferable to declare the loop variable in the loop header:

\[
\text{for (int var=low; var<upper; var++) } \{ \\
\}
\]

The variable only has meaning inside the loop so it should only be defined there.

However, it can also be defined outside the loop:

\[
\text{int var;} \\
\text{for (var=low; var<upper; var++) } \{ \}
\]

You will see an example where this makes sense below.

**No stopping test**  The stopping test can be omitted

\[
\text{for (int var=low; } ; \text{ var++) } \{ \ldots \}
\]

if the loops ends in some other way. You’ll see this later.

**Count down**  The stopping test doesn’t need to be an upper bound. Here is an example of a loop that counts down to a lower bound.

\[
\text{for (int var=high; var\geq low; var--) } \{ \ldots \}
\]

**Stopping test is pre-test**  The test is performed before each iteration:
6.1. The ‘for’ loop

Code:
```cpp
cout << "before the loop" << endl;
for (int i=5; i<4; i++)
    cout << "in iteration " << i << endl;
cout << "after the loop" << endl;
```

Output
[basic] pretest:
before the loop
after the loop

**Loop body** The loop body can be a single statement:
```cpp
int s{0};
for (int i=0; i<N; i++)
    s += i;
```
or a block:
```cpp
int s{0};
for (int i=0; i<N; i++) {
    int t = i*i;
    s += t;
}
```

### 6.1.1 Loop syntax

The loop variable is typically an integer. You can use floating point numbers, but this may complicate the stopping test:
```cpp
for (float x=.1; x<=.5; x+=.1)
```
Because of numerical rounding it is not clear when this loop will end.

Quite often, the loop body will contain another loop. For instance, you may want to iterate over all elements in a matrix. Both loops will have their own unique loop variable.
```cpp
for (int row=0; row<m; row++)
    for (int col=0; col<n; col++)
        ...
```
This is called loop nest; the row-loop is called the outer loop and the col-loop the inner loop.

Traversing an index space (whether that corresponds to an array object or not) by row, col is called the lexicographic ordering. Below you’ll see that there are also different ways.

**Exercise 6.6.** Write an i,j loop nest that prints out all pairs with

\[ 1 \leq i, j \leq 10, \quad j \leq i. \]

Output one line for each i value.

Now write an i,j loop that prints all pairs with

\[ 1 \leq i, j \leq 10, \quad |i - j| < 2, \]
again printing one line per \( i \) value. Food for thought: this exercise is definitely easiest with a conditional in the inner loop, but can you do it without?

Figure 6.1: Lexicographic and diagonal ordering of an index set

Figure 6.1 illustrates that you can look at the \( i, j \) indices by row/column or by diagonal. Just like rows and columns being defined as \( i = \) constant and \( j = \) constant respectively, a diagonal is defined by \( i + j = \) constant.

Figure 6.2: Illustration of the second part of exercise 6.8

**6.2 Looping until**

The basic for loop looks pretty deterministic: a loop variable ranges through a more-or-less prescribes set of values. This is appopriate for looping over the elements of an array, but not if you are coding some process that needs to run until some dynamically determined condition is satisfied. In this section you will see some ways of coding such cases.

First of all, the stopping test in the ‘for’ loop is optional, so you can write an indefinite loop as:

\[
\mathbf{for} \ (\text{int} \ \text{var}=\text{low}; \ \text{var}=\text{var}+1) \ {\ldots} \ 
\]

How do you end such a loop? For that you use the \texttt{break} statement. If the execution encounters this statement, it will continue with the first statement after the loop.
6.2. Looping until

```c
for (int var=low; ; var=var+1) {
    // statements;
    if (some_test) break;
    // more statements;
}
```

For the following exercise, see figure 6.2 for inspiration.

**Exercise 6.7.** Write a double loop over $0 \leq i, j < 10$ that prints all pairs $(i, j)$ where the product $i \cdot j > 40$.

*You can base this off the file ijloop.cxx.cxx.*

**Exercise 6.8.** Write a double loop over $0 \leq i, j < 10$ that prints the first pair where the product of indices satisfies $i \cdot j > N$, where $N$ is a number your read in. A good test case is $N = 40$.

Secondly, find a pair with $i \cdot j > N$, but with the smallest value for $i + j$. (If there is more than one pair, report the one with lower $i$ value.) Can you traverse the $i, j$ indices such that they first enumerate all pairs $i + j = 1$, then $i + j = 2$, then $i + j = 3$ et cetera? Hint: write a loop over the sum value $1, 2, 3, \ldots$, then find $i, j$.

You program should print out both pairs, each on a separate line, with the numbers separated with a comma, for instance $8, 5$.

**Exercise 6.9.** All three parts of a loop header are optional. What would be the meaning of

```c
for (;) { /* some code */ }
```

*Where did the break happen?*

Suppose you want to know what the loop variable was when the break happened. You need the loop variable to be global:

```c
int var;
... code that sets var ...
for ( ; var<upper; var++) {
    ... statements ...
    if (some condition) break
    ... more statements ...
}
... code that uses the breaking value of var ...
```

In other cases: define the loop variable in the header!

**Test in the loop header**

If the test comes at the start or end of an iteration, you can move it to the loop header:
6. Looping

```cpp
bool need_to_stop(false);
for (int var=low; !need_to_stop ; var++) {
    ... some code ...
    if (some condition)
        need_to_stop = true;
}
```

Another mechanism to alter the control flow in a loop is the `continue` statement. If this is encountered, execution skips to the start of the next iteration.

**Skip iteration**

```cpp
for (int var=low; var<N; var++) {
    statement;
    if (some_test) {
        statement;
        statement;
    }
}
```

Alternative:

```cpp
for (int var=low; var<N; var++) {
    statement;
    if (!some_test) continue;
    statement;
    statement;
}
```

The only difference is in layout.

**While loop**

The other possibility for ‘looping until’ is a `while` loop, which repeats until a condition is met.

Syntax:

```cpp
while (condition) {
    statements;
}
```

or

```cpp
do {
    statements;
} while (condition);
```

The while loop does not have a counter or an update statement; if you need those, you have to create them yourself.

The two while loop variants can be described as ‘pre-test’ and ‘post-test’. The choice between them entirely depends on context.

**Pre-test while loop**

```cpp
float money = inheritance();
while (money < 1.e+6)
    money += on_year_savings();
```
6.2. Looping until

Here is an example in which the second syntax is more appropriate.

**While syntax 1**

**Code:**
```cpp
cout << "Enter a positive number: " ;
cin >> invar; cout << endl;
cout << "You said: " << invar << endl;
while (invar<=0) {
    cout << "Enter a positive number: " ;
cin >> invar; cout << endl;
cout << "You said: " << invar << endl;
}
cout << "Your positive number was " 
    << invar << endl;
```

**Output**
```plaintext
[basic] whiledo:
Enter a positive number:
You said: -3
Enter a positive number:
You said: 0
Enter a positive number:
You said: 2
Your positive number was 2
```

Problem: code duplication.

**While syntax 2**

**Code:**
```cpp
int invar;
do {
    cout << "Enter a positive number: " ;
cin >> invar; cout << endl;
cout << "You said: " << invar << endl;
} while (invar<=0);
cout << "Your positive number was: " 
    << invar << endl;
```

**Output**
```plaintext
[basic] dowhile:
Enter a positive number:
You said: -3
Enter a positive number:
You said: 0
Enter a positive number:
You said: 2
Your positive number was: 2
```

The post-test syntax leads to more elegant code.

**Exercise 6.10.** At this point you are ready to do the exercises in the prime numbers project, section 52.3.

**Exercise 6.11.** A horse is tied to a post with a 1 meter elastic band. A spider that was sitting on the post starts walking to the horse over the band, at 1cm/sec. This startles the horse, which runs away at 1m/sec. Assuming that the elastic band is infinitely stretchable, will the spider ever reach the horse?

**Exercise 6.12.** One bank account has 100 dollars and earns a 5 percent per year interest rate. Another account has 200 dollars but earns only 2 percent per year. In both cases the interest is deposited into the account. After how many years will the amount of money in the first account be more than in the second? Solve this with a while loop.

Food for thought: compare solutions with a pre-test and post-test, and also using a for-loop.
6. Looping

6.3 Advanced topics

6.3.1 Parallelism

At the start of this chapter we mentioned the following examples of loops:

• A time-dependent numerical simulation executes a fixed number of steps, or until some stopping test.
• Recurrences:

\[ x_{i+1} = f(x_i). \]

• Inspect or change every element of a database table.

The first two cases actually need to be performed in sequence, while the last one corresponds more to a mathematical ‘forall’ quantor. You will later learn two different syntaxes for this in the context of arrays. This difference can also be exploited when you learn parallel programming. Fortran has a \textit{do concurrent} loop construct for this.

6.4 Exercises

Exercise 6.13. Find all triples of integers \( u, v, w \) under 100 such that \( u^2 + v^2 = w^2 \). Make sure you omit duplicates of solutions you have already found.

Exercise 6.14. The integer sequence

\[ u_{n+1} = \begin{cases} 
    u_n/2 & \text{if } u_n \text{ is even} \\
    3u_n + 1 & \text{if } u_n \text{ is odd}
\end{cases} \]

leads to the \textit{Collatz conjecture}: no matter the starting guess \( u_1 \), the sequence \( n \mapsto u_n \) will always terminate at 1.

\[ \begin{align*}
\text{5} & \rightarrow 16 & \rightarrow 8 & \rightarrow 4 & \rightarrow 2 & \rightarrow 1 \\
\text{7} & \rightarrow 22 & \rightarrow 11 & \rightarrow 34 & \rightarrow 17 & \rightarrow 52 & \rightarrow 26 & \rightarrow 13 & \rightarrow 40 & \rightarrow 20 & \rightarrow 10 & \rightarrow 5 & \ldots \\
\end{align*} \]

(What happens if you keep iterating after reaching 1?)

Try all starting values \( u_1 = 1, \ldots, 1000 \) to find the values that lead to the longest sequence: every time you find a sequence that is longer than the previous maximum, print out the starting number.
Exercise 6.15. Large integers are often printed with a comma (US usage) or a period (European usage) between all triples of digits. Write a program that accepts an integer such as 2542981 from the input, and prints it as 2,542,981.

Exercise 6.16. Root finding. For many functions $f$, finding their zeros, that is, the values $x$ for which $f(x) = 0$, can not be done analytically. You then have to resort to numerical root finding schemes. In this exercise you will implement a simple scheme.

Suppose $x_-, x_+$ are such that
\[ x_- < x_+, \quad f(x_-) \cdot f(x_+) < 0, \]
that is, the function values are of opposite sign. Then there is a zero in the interval $(x_-, x_+)$. Try to find this zero by looking at the halfway point, and based on the function value there, considering the left or right interval.

- How do you find $x_-, x_+$? This is tricky in general; if you can not find them in the interval $[-10^6, +10^6]$, halt the program.
- Finding the zero exactly may also be tricky or maybe impossible. Stop your program if $|x_+ - x_-| < 10^{-10}$.

The website [http://www.codeforwin.in/2015/06/for-do-while-loop-programming-exercises.html](http://www.codeforwin.in/2015/06/for-do-while-loop-programming-exercises.html)
6. Looping
Chapter 7

Functions

A function (or subprogram) is a way to abbreviate a block of code and replace it by a single line. This is foremost a code structuring device: by giving a function a relevant name you introduce the terminology of your application into your program.

- Find a block of code that has a clearly identifiable function.
- Turn this into a function: the function definition will contain that block, plus a header and (maybe) a return statement.
- The function definition is placed before the main program.
- The function is called by its name.

Introducing a function

By introducing a function name you have introduced abstraction: your program now uses terms related to your problem, and not only for and int and such.

7.1 Function definition and call

There are two sides to a function:

- The function definition is done once, typically above the main program;
- a function call to any function can happen multiple times, inside the main or inside other functions.

Program without functions
7. Functions

Example: zero-finding through bisection.

\[ f(x) = 0, \quad f(x) = x^3 - x^2 - 1 \]

Step 1: everything in the main program.

```
Code:
float left{0.}, right{2.}, mid;
while (right-left>.1) {
    mid = (left+right)/2.;
    float fmid =
        mid*mid*mid - mid*mid-1;
    if (fmid<0)
        left = mid;
    else
        right = mid;
}
cout << "Zero happens at: " << mid << endl;
```

Output
```
[func] bisect1:
Zero happens at: 1.4375
```

Introducing functions, step 1

Introduce function for the expression \(m^3 - m^2 - 1\): 
```c
float f(float x) {
    return x*x*x - x*x-1;
};
```

Used in main:

Introducing Functions, step 2

Add function for zero finding:
```
float f(float x) {
    return x*x*x - x*x-1;
};
float find_zero_between
(float l,fload r) {
    float mid;
    while (r-l>.1) {
        mid = (l+r)/2.;
        float fmid = f(mid);
        if (fmid<0)
            l = mid;
        else
            r = mid;
    }
    return mid;
};
```

The main no longer contains any implementation details (local variables, method used):
```
int main() {
    float left{0.}, right{2.};
    float zero =
        find_zero_between(left,right);
    cout << "Zero happens at: " << zero << endl;
    return 0;
}
```
Exercise 7.1. Take the source of the previous example, and introduce functions `new_l`, `new_r` used as:

```plaintext
l = new_l(l, mid, fmid);
r = new_r(r, mid, fmid);
```

You can base this off the file `bisect.cxx.cxx`.

Question: you could leave out `fmid` from these functions. Write this variant. Why is this not a good idea?

In this example, the function definition consists of:

- The keyword `float` indicates that the function returns a `float` result to the calling code.
- The name `find_zero_between` is picked by you.
- The parenthetical `(int n)` is called the 'parameter list': it says that the function takes an `int` as input. For purposes of the function, the `int` will have the name `n`, but this is not necessarily the same as the name in the main program.
- The ‘body’ of the function, the code that is going to be executed, is enclosed in curly brackets.
- A ‘return’ statement that transfers a computed result out of the function.

The function call consists of:

- The name of the function, and
- In between parentheses, any input argument(s).

The function call can stand on its own, or can be on the right-hand-side of an assignment.

### 7.1.1 Why use functions?

In many cases, code that is written using functions can also be written without. So why would you use functions? There are several reasons for this.

Function can be motivated as making your code more structured and intelligible. The source where you use the function call becomes shorter, and the function name makes the code more descriptive. This is sometimes called ‘self-documenting code’.

Sometimes introducing a function can be motivated from a point of code reuse: if the same block of code appears in two places in your source (this is known as code duplication), you replace this by one function definition, and two (single line) function calls. The two occurrences of the function code do not have to be identical:

### Code reuse

Suppose you do the same computation twice:

```plaintext
double x, y, v, w;
y = .... computation from x ....
w = .... same computation, but from v ....
```

With a function this can be replaced by:

```plaintext
double computation(double in) {
    return .... computation from ‘in’ ....
}
```
7. Functions

```cpp
y = computation(x);
w = computation(v);
```

### Code reuse

Example: multiple norm calculations:

Repeated code:

```cpp
float s = 0;
for (int i=0; i<x.size(); i++)
s += abs(x[i]);
cout << "One norm x: " << s << endl;
s = 0;
for (int i=0; i<y.size(); i++)
s += abs(y[i]);
cout << "One norm y: " << s << endl;
```

Becomes:

```cpp
float OneNorm( vector<float> a ) {
float sum = 0;
for (int i=0; i<a.size(); i++)
sum += abs(a[i]);
return sum;
}
```

(Don’t worry about array stuff in this example)

A final argument for using functions is code maintainability:

- Easier to debug: if you use the same (or roughly the same) block of code twice, and you find an error, you need to fix it twice.
- Maintainance: if a block occurs twice, and you change something in such a block once, you have to remember to change the other occurrence(s) too.
- Localization: any variables that only serve the calculation in the function now have a limited scope.

```cpp
void print_mod( int n, int d ) {
int m = n % d;
cout << "The modulus of " << n << " and " << d << " is " << m << endl;
}
```

### Review 7.2. True or false?

- The purpose of functions is to make your code shorter.
- Using functions makes your code easier to read and understand.
- Functions have to be defined before you can use them.
- Function definitions can go inside or outside the main program.

7.2 Anatomy of a function definition and call

Loosely, a function takes input and computes some result which is then returned. Formally, a function definition
7.2. Anatomy of a function definition and call

```c
int compute(float x, char c) {
    /* code */
    return somevalue;
}
```

consists of:
- **function result type**: you need to indicate the type of the result;
- **name**: you get to make this up;
- **zero or more function parameters**. These describe how many function arguments you need to supply as input to the function. Parameters consist of a type and a name. This makes them look like variable declarations, and that is how they function. Parameters are separated by commas. Then follows the:
- **function body**: the statements that make up the function. The function body is a scope: it can have local variables. (You can not nest function definitions.)
- **a return statement**. Which doesn’t have to be the last statement, by the way.

The function can then be used in the main program, or in another function

### Function call

The function call

1. copies the value of the function argument to the function parameter;
2. causes the function body to be executed, and
3. the function call is replaced by whatever you return.
4. (If the function does not return anything, for instance because it only prints output, you declare the return type to be void.)

A function body defines a scope: the local variables of the function calculation are invisible to the calling program.

Functions can not be nested: you can not define a function inside the body of another function.

#### 7.2.1 Another option for defining functions

The C++ compiler translates your code in one pass: it goes from top to bottom through your code. This means you can not make reference to anything, such as a function name, that you haven’t defined yet. This is why above we said that the function definition has to come before the main program.

This is not entirely true: the translation of a program that uses a function can proceed once the compiler know its name, and the types of the inputs and result. Just like you can declare a variable and set its value later, you can declare the existence of a function and give its definition later. The resulting code looks like:

```c
int my_computation(int);
int main() {
    int result;
    result = my_computation(5);
    return 0;
}
int my_computation(int i) {
    return i+3;
}
```
7. Functions

The line above the main program is called a function header or function prototype. See chapter 19 for more details.

7.3 Void functions

Some functions do not return anything, for instance because only write output to screen or file. In that case you define the function to be of type void.

Functions without input, without return result

```c++
void print_header() {
    cout << "****************" << endl;
    cout << "* Output *" << endl;
    cout << "****************" << endl;
}
int main() {
    print_header();
    cout << "The results for day 25:" << endl;
    // code that prints results ....
    return 0;
}
```

Void function with input

```c++
void print_result(int day, float value) {
    cout << "****************" << endl;
    cout << "* Output *" << endl;
    cout << "****************" << endl;
    cout << "The results for day " << day << ":" << endl;
    cout << " " << value << endl;
}
int main() {
    print_result(25, 3.456);
    return 0;
}
```

Review 7.3. True or false?

- A function can have only one input
- A function can have only one return result
- A void function can not have a return statement.

7.4 Parameter passing

C++ functions resemble mathematical functions: you have seen that a function can have an input and an output. In fact, they can have multiple inputs, separated by commas, but they have only one output. (Later you will learn how to pack together multiple outputs.)

\[ a = f(x, y, i, j) \]

We start by studying functions that look like these mathematical functions. They involve a parameter passing mechanism called passing by value. Later we will then look at passing by reference.
7.4. Parameter passing

7.4.1 Pass by value

The following style of programming is very much inspired by mathematical functions, and is known as functional programming\textsuperscript{1}.

• A function has one result, which is returned through a return statement. The function call then looks like
  \[ y = f(x_1, x_2, x_3); \]

• Example:

\begin{verbatim}
Code:
double squared( double x ) {
    double y = x*x;
    return y;
}
/* ... */
number = 5.1;
cout << "Input starts as: "
    << number << endl;
other = squared(number);
cout << "Output var is: "
    << other << endl;
cout << "Input var is now: "
    << number << endl;
Output
[func] passvalue:
Input starts as: 5.1
Output var is: 26.01
Input var is now: 5.1
\end{verbatim}

• The definition of the C++ parameter passing mechanism says that input arguments are copied to the function, meaning that they don’t change in the calling program:

\begin{verbatim}
Code:
double squared( double x ) {
    x = x*x;
    return x;
}
/* ... */
number = 5.1;
cout << "Input starts as: "
    << number << endl;
other = squared(number);
cout << "Output var is: "
    << other << endl;
cout << "Input var is now: "
    << number << endl;
Output
[func] passvalue:
Input starts as: 5.1
Output var is: 26.01
Input var is now: 5.1
\end{verbatim}

We say that the input argument is passed by value: its value is copied into the function. In this example, the function parameter \( x \) acts as a local variable in the function, and it is initialized with a copy of the value of \( \text{number} \) in the main program.

Later we will worry about the cost of this copying.

\textsuperscript{1} There is more to functional programming. For instance, strictly speaking your whole program needs to be based on function calling; there is no other code than function definitions and calls.
7. Functions

Exercise 7.4. Write two functions

```c
int biggest(int i, int j);
int smallest(int i, int j);
```

and a program that uses them to swap two values:

```c
int i = 5, j = 17;
... biggest(i, j) ...
... smallest(i, j) ...
if (i==17 && j==5)
    cout « "Correct!" « endl;
```

Passing a variable to a routine passes the value; in the routine, the variable is local. So, in this example the value of the argument is not changed:

```c
void change_scalar(int i) {
    i += 1;
}
/* ... */
number = 3;
cout « "Number is 3: "
    « number « endl;
change_scalar(number);
cout « "is it still 3? Let's see: "
    « number « endl;
```

Exercise 7.5. If you are doing the prime project (chapter 52) you can now do exercise 52.6.

Background Square roots through Newton

Early computers had no hardware for computing a square root. Instead, they used Newton’s method. Suppose you have a value \( y \) and you want want to compute \( x = \sqrt{y} \). This is equivalent to finding the zero of

\[
f(x) = x^2 - y
\]

where \( y \) is fixed. To indicate this dependence on \( y \), we will write \( f_y(x) \). Newton’s method then finds the zero by evaluating

\[
x_{\text{next}} = x - f_y(x)/f'_y(x)
\]

until the guess is accurate enough, that is, until \( f_y(x) \approx 0 \).

Exercise 7.6.

- Write functions \( f(x, y) \) and \( \text{deriv}(x, y) \), that compute \( f_y(x) \) and \( f'_y(x) \) for the definition of \( f_y \) above.
7.4. Parameter passing

- Read a value \( y \) and iterate until \(|f(x,y)| < 10^{-5}\). Print \( x \).
- Second part: write a function \texttt{newton_root} that computes \( \sqrt{y} \).

### 7.4.2 Pass by reference

Having only one output is a limitation on functions. Therefore there is a mechanism for altering the input parameters and returning (possibly multiple) results that way. You do this by not copying values into the function parameters, but by turning the function parameters into aliases of the variables at the place where the function is called.

We need the concept of a reference: another variable to refers to the same ‘thing’ as another, already existing, variable.

**Reference**

A reference is indicated with an ampersand in its definition, and it acts as an alias of the thing it references.

**Code:**

```c++
int i;
int &ri = i;
i = 5;
cout << i << "," << ri << endl;
i *= 2;
cout << i << "," << ri << endl;
ri -= 3;
cout << i << "," << ri << endl;
```

*(You will not use references often this way.)*

**Reference create by initialize**

Correct:

```c++
float x{1.5};
float &xref = x;
```

Not correct:

```c++
float x{1.5};
float &xref;
xref = x;
float &threeref = 3; // WRONG: only reference to `lvalue`
```

If you already know about pointers, you may wonder about the similarities.

**Reference vs pointer**

- There are no ‘null’ references. There is a \texttt{nullptr}.
- References are bound when they are created.
- You can not change what a reference is bound to; the pointer target can change.
- Reference syntax is cleaner.
- Pointer use has implications about ownership: use only for specific purposes.

Victor Eijkhout
You can make a function parameter into a reference of a variable in the main program. This makes the function parameter into another name referring to the same thing.

**Parameter passing by reference**

The function parameter `n` becomes a reference to the variable `i` in the main program:

```c
void f(int &n) {  
    n = /* some expression */ ;
};  
int main() {  
    int i;  
    f(i);  
    // i now has the value that was set in the function  
}
```

Using the ampersand, the parameter is **passed by reference**: instead of copying the value, the function receives a reference, so that the parameter becomes a reference to the thing in the **calling environment**.

**Remark 2** The pass by reference mechanism in C was different and should not be used in C++. In fact it was not a true pass by reference, but passing an address by value.

We also the following terminology for function parameters:

- **input** parameters: passed by value, so that it only functions as input to the function, and no result is output through this parameter;
- **output** parameters: passed by reference so that they return an ‘output’ value to the program.
- **throughput** parameters: these are passed by reference, and they have an initial value when the function is called. In C++, unlike Fortran, there is no real separate syntax for these.

**Pass by reference example 1**

```c
void f( int &i ) {  
    i = 5;
};  
int main() {  
    int var = 0;  
    f(var);  
    cout << var << endl;
}
```

Compare the difference with leaving out the reference.

As an example, consider a function that tries to read a value from a file. With anything file-related, you always have to worry about the case of the file not existing and such. So our function returns:

- a boolean value to indicate whether the read succeeded, and
- the actual value if the read succeeded.

The following is a common idiom, where the success value is returned through the **return** statement, and the value through a parameter.

**Advanced note:** There are other, more advanced solutions for this. You could for instance use tuples (section 24.4), or, in C++17, **variant** (section 24.5.3).
Pass by reference example 2

```cpp
bool can_read_value(int &value) {
    // this uses functions defined elsewhere
    int file_status = try_open_file();
    if (file_status==0) {
        value = read_value_from_file();
        return file_status==0;
    }

    // this uses functions defined elsewhere
    int n;
    if (!can_read_value(n)) {
        // if you can’t read the value, set a default
        n = 10;
    }
    // do something with ’n’ ....
    return 0;
}
```

Exercise 7.7. Write a `void` function `swap` of two parameters that exchanges the input values:

<table>
<thead>
<tr>
<th>Code</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
</tbody>
</table>
| ```
cout << i << "," << j << endl;
swap(i,j);
cout << i << "," << j << endl;
``` |        |
| ```
cout << i << "," << j << endl;
``` | ```
[func] swap:
1,2
2,1
``` |

Exercise 7.8. Write a divisibility function that takes a number and a divisor, and gives:
- a `bool` return result indicating that the number is divisible, and
- a remainder as output parameter.

<table>
<thead>
<tr>
<th>Code</th>
<th>Output</th>
</tr>
</thead>
</table>
| ```
cout << number;
if (is_divisible(number,divisor,remainder)) {
cout << " is divisible by ";
} else {
cout << " has remainder ";
    cout << remainder << " from ";
cout << divisor << endl;
``` | ```
[func] divisible:
8 has remainder 2 from 3
8 is divisible by 4
``` |

Exercise 7.9. If you are doing the geometry project, you should now do the exercises in section 53.1.
7. Functions

7.5 Recursive functions

In mathematics, sequences are often recursively defined. For instance, the sequence of factorials $n \mapsto f_n \equiv n!$ can be defined as

$$f_0 = 1, \quad \forall n > 0: f_n = n \times f_{n-1}.$$ 

Instead of using a subscript, we write an argument in parentheses

$$F(n) = n \times F(n-1) \quad \text{if } n > 0, \text{ otherwise 1}$$

This is a form that can be translated into a C++ function. The header of a factorial function can look like:

```cpp
int factorial(int n)
```

So what would the function body be? We need a `return` statement, and what we return should be $n \times F(n-1)$:

```cpp
int factorial(int n) {
    return n * factorial(n - 1);
} // almost correct, but not quite
```

So what happens if you write

```cpp
int f3; f3 = factorial(3);
```

Well,

- The expression `factorial(3)` calls the `factorial` function, substituting 3 for the argument $n$.
- The return statement returns $n \times \text{factorial}(n-1)$, in this case $3 \times \text{factorial}(2)$.
- But what is `factorial(2)`? Evaluating that expression means that the `factorial` function is called again, but now with $n$ equal to 2.
- Evaluating `factorial(2)` returns $2 \times \text{factorial}(1)$,
- ... which returns $1 \times \text{factorial}(0)$,
- ... which returns ...
- Uh oh. We forgot to include the case where $n$ is zero. Let’s fix that:

```cpp
int factorial(int n) {
    if (n == 0)
        return 1;
    else
        return n * factorial(n - 1);
}
```

- Now `factorial(0)` is 1, so `factorial(1)` is $1 \times \text{factorial}(0)$, which is 1,
- ... so `factorial(2)` is 2, and `factorial(3)` is 6.

Exercise 7.10. The sum of squares:

$$S_n = \sum_{n=1}^{N} n^2$$

can be defined recursively as

$$S_1 = 1, \quad S_n = n^2 + S_{n-1}.$$
Write a recursive function that implements this second definition. Test it on numbers that are input interactively.

Then write a program that prints the first 100 sums of squares.

How many squares do you need to sum before you get overflow? Can you estimate this number without running your program?

**Exercise 7.11.** It is possible to define multiplication as repeated addition:

**Code:**

```c++
int times(int number, int mult) {
    cout << "(" << mult << ")";
    if (mult == 1)
        return number;
    else
        return number + times(number, mult - 1);
}
```

**Output**

- **func** mult:
  - Enter number and multiplier recursive multiplication of 7 and 5: (5)(4)(3)(2)(1)35

Extend this idea to define powers as repeated multiplication.

*You can base this off the file mult.cxx.*

**Exercise 7.12.** The *Egyptian multiplication* algorithm is almost 4000 years old. The result of multiplying \(x \times n\) is:

- if \(n\) is even:
  - twice the multiplication \(x \times (n/2)\);
- otherwise:
  - \(x\) plus the multiplication \(x \times (n - 1)\)

Extend the code of exercise 7.11 to implement this.

Food for thought: discuss the computational aspects of this algorithm to the traditional one of repeated addition.

**Exercise 7.13.** Write a recursive function for computing Fibonacci numbers:

\[
F_0 = 1, \quad F_1 = 1, \quad F_n = F_{n-1} + F_{n-2}
\]

First write a program that computes \(F_n\) for a value \(n\) that is input interactively.

Then write a program that prints out a sequence of Fibonacci numbers; set interactively how many.

**Remark 3** *A function does not need to call itself directly to be recursive; if it does so indirectly we can call this mutual recursion.*

*Victor Eijkhout*
Remark 4 If you let your Fibonacci program print out each time it computes a value, you’ll see that most values are computed several times. (Math question: how many times?) This is wasteful in running time. This problem is addressed in section 65.3.1.

7.6 Lambdas

The mechanism of lambda expressions (added in C++11) makes dynamic definition of functions possible.

A simple example

You can define a function and apply it:

```cpp
double f(double x) { return 2*x; }
y = f(3.7);
```

or you can apply the function recipe directly:

```cpp
y = [](double x) -> double { return 2*x; }(3.7);
```

This example is of course fairly pointless, but it illustrates the syntax of a lambda function:

```
[capture] (inputs) -> outtype { definition };
```

- The square brackets, in this case, but not in general, empty, are the capture part;
- then follows the usual argument list;
- with a stylized arrow you can indicate the return type, but this is optional if the compiler can figure it out by itself;
- and finally the usual function body, include return statement for non-void functions.

Remark 5 Lambda functions are sometimes called closures, but this term has a technical meaning in programming language theory, that only partly coincides with C++ lambda functions.

For a slightly more useful example, we can assign the lambda function to a variable, and repeatedly apply it.

Assign lambda to variable

```cpp
auto f = [](double x) -> double { return 2*x; }; 
y = f(3.7); 
z = f(4.9);
```

(For technical reasons it is necessary to use auto here. Otherwise this is a typed variable declaration as you have seen before.)

Exercise 7.14. The Newton method (HPSC-22) for finding the zero of a function $f$, that is, finding the $x$ for which $f(x) = 0$, can be programmed by supplying the function and its derivative:

```cpp
double f(double x) { return x*x-2; };
double g(double x) { return 2*x; };
```
and the algorithm:

```cpp
double x{1.};
while (true) {
    auto fx = f(x);
    cout << "f( " << x << " ) = " << fx << "\n";
    if (abs(fx)<1.e-10) break;
    x = x - fx/g(x);
}
```

Rewrite this code to use lambda functions for $f$ and $g$.

You can base this off the file `newton.cxx`.

### 7.6.1 Passing lambdas around

Above, when we assigned a lambda function to a variable, we used `auto` for the type. The reason for this is that each lambda function gets its own unique type, that is dynamically generated. But that makes it hard to pass that variable to a function: what type do we declare the parameter to be?

The way out is to use the `functional` header:

```cpp
#include <functional>
using std::function;
```

With this, you can declare parameters by their signature:

```cpp
double find_zero(
    function<double(double)> f,
    function<double(double)> g)
```

Exercise 7.15. Rewrite the Newton exercise above to use a function with this prototype. Call the function directly with the lambda functions as arguments, that is, without assigning them to variables.

### 7.6.2 Captures

A non-trivial use of lambdas uses the capture to fix one argument of a function. Let’s say we want a function that computes exponentials for some fixed exponent value. We take the `cmath` function

```cpp
pow(x, exponent);
```

and fix the exponent:

```cpp
int exponent=5;
auto powerfive =
    [exponent] (float x) -> float {
        return pow(x, exponent);
    };
```

Now `powerfunction` is a function of one argument, which computes that argument to a fixed power.
Exercise 7.16. Extend the newton exercise to compute roots in a loop:

```cpp
for (int n=2; n<=8; n++) {
    cout << \\
    "sqrt(\" << n << ") = \"
    << find_zero( \\
    /* ... */
    )
    << "\n";
}
```
Without lambdas, you would define a function

```cpp
double f( double x, int n );
```
However, the `find_zero` function takes a function of only a real argument. Use a capture to make `f` dependent on the integer parameter.

Exercise 7.17. You don’t need the gradient as an explicit function: you can approximate it as

\[
\frac{f'(x)}{h} = \frac{f(x + h) - f(x)}{h}
\]
for some value of `h`.
Write a version of the root finding function

```cpp
double find_zero( function< double(double) > f, double h=.001 );
```
that uses this. Do not reimplement the whole newton method: instead create a lambda for the gradient and pass it to the root finder you coded earlier.

### 7.6.3 Lambda members of classes

Storing a lambda in a class is hard because it has unique type. Solution: use `std::function`.

#### Lambda in object

A set of integers, with a test on which ones can be admitted:

```cpp
#include <functional>
using std::function;
/* ... */
class SelectedInts {
private:
  vector<int> bag;
  function< bool(int) > selector;
public:
  SelectedInts ( function< bool(int) > f ) {
    selector = f;
  }
  void add(int i) {
    if (selector(i))
      bag.push_back(i);
  }
  int size() {
    return bag.size(); }
  std::string string() {
    std::string s;
    for ( int i : bag )
      s += to_string(i)+" ";
    return s;
  }
};
```
### 7.6. Lambdas

#### Illustration

**Code:**

```cpp
cout << "Give a divisor: ";
cin >> divisor; cout << endl;
cout << ". using " << divisor << endl;
SelectedInts multiples
( [divisor] (int i) -> bool {
    return i%divisor==0; } );
for (int i=1; i<50; i++)
multiples.add(i);
```

**Output**

```
[func lambdafun:
Give a divisor: .. using 7
Multiples of 7: 7 14 21 28 35 42 49
```

### 7.6.4 Generic lambdas

The `auto` keyword can be used, almost abused, for **generic lambdas**:

```cpp
auto compare = [] (auto a, auto b) { return a<b; };
```

Here the return type is clear, but the input types are generic.

### 7.6.5 Capture by reference

Normally, captured variables are copied by value. You can capture them by reference by prefixing an ampersand to them

```cpp
auto maybeinc = [&count] (int i) {
    if (f(i)) count++;
}
```

**Remark 6 check on this** The lambda expression also needs to be marked `mutable` because by default it is a `const`.

**Code:**

```cpp
vector<int> moreints{8,9,10,11,12};
int count{0};
for_each
{ moreints.begin(),moreints.end(),
    [&count] (int x) {
        if (x%2==0)
            count++;
    } );
cout << "number of even: " << count << endl;
```

**Output**

```
[stl counteach:
number of even: 3
```

The **algorithm** header (section 14.2) contains a number of functions that naturally use lambdas. For instance, `any_of` can test whether any element of a `vector` satisfies a condition. You can then use a lambda to specify the `bool` function that tests the condition.

Victor Eijkhout 93
7. Functions

7.6.6 C-style function pointers

The C language had a – somewhat confusing – notation for function pointers. If you need to interface with code that uses them, it is possible to use lambda functions to an extent: lambdas without captures can be converted to a function pointer.

7.7 Leftover function topics

7.7.1 Default arguments

Default arguments

Functions can have default argument(s):

```
double distance(double x, double y=0) {
    return sqrt((x-y)*(x-y));
}
```

```
... 
    d = distance(x); // distance to origin
    d = distance(x,y); // distance between two points
```

Any default argument(s) should come last in the parameter list.

7.7.2 Polymorphic functions

Polymorphic functions

You can have multiple functions with the same name:

```
double average(double a, double b) {
    return (a+b)/2;
}
double average(double a, double b, double c) {
    return (a+b+c)/3;
}
```

Distinguished by type or number of input arguments: can not differ only in return type.

```
int f(int x);
string f(int x); // DOES NOT WORK
```

(More about strings later.)

Useful idiom

Don’t trace a function unless I say so:

```
void dosomething(double x, bool trace=false) {
    if (trace) // report on stuff
    }

int main() {
    dosomething(1); // this one I trust
    dosomething(2); // this one I trust
    dosomething(3, true); // this one I want to trace!
    dosomething(4); // this one I trust
    dosomething(5); // this one I trust
    ```
7.7.3 Stack overflow

So far you have seen only very simple recursive functions. Consider the function

\[ g_n = (n-1) \cdot g(n-1), \quad g(1) = 1 \]

and its implementation:

```cpp
int multifact (int n) {
    if (n==1)
        return 1;
    else {
        int oneless = n-1;
        return oneless * multifact(oneless);
    }
}
```

Now the function has a local variable. Suppose we compute \( g(3) \). That involves

```cpp
int oneless = 2;
```

and then the computation of \( g_2 \). But that computation involved

```cpp
int oneless = 1;
```

Do we still get the right result for \( g_3 \)? Is it going to compute \( g_3 = 2 \cdot g_2 \) or \( g_3 = 1 \cdot g_2 \)?

Not to worry: each time you call `multifact` a new local variable `oneless` gets created ‘on the stack’. That is good, because it means your program will be correct\(^2\), but it also means that if your function has both

- a large amount of local data, and
- a large recursion depth,

it may lead to stack overflow.

7.8 Library functions

7.8.1 Random function

There is an easy (but not terribly great) random number generator that works the same as in C (for a better generator, see section 24.8):

```cpp
#include <random>
using std::rand;
float random_fraction = (float)rand() / (float)RAND_MAX;
```

The function `rand` yields an `int` – a different one every time you call it – in the range from zero to `RAND_MAX`. Using scaling and casting you can then produce a fraction between zero and one with the above code.

If you run your program twice, you will twice get the same sequence of random numbers. That is great for debugging your program but not if you were hoping to do some statistical analysis. Therefore you can set the random number seed from which the random sequence starts by the `srand` function. Example:

\[ \text{2. Historical note: very old versions of Fortran did not do this, and so recursive functions were basically impossible.} \]

Victor Eijkhout
seeds the random number generator from the current time. This call should happen only once, typically somewhere high up in your main.

### 7.9 Review questions

**Review 7.18.** What is the output of the following programs (assuming the usual headers):

```cpp
int add1(int i) {
    return i+1;
}

int main() {
    int i=5;
    cout << i << endl;
}
```

```cpp
void add1(int i) {
    i = i+1;
}

int main() {
    int i=5;
    add1(i);
    cout << i << endl;
}
```

```cpp
void add1(int &i) {
    i = i+1;
}

int main() {
    int i=5;
    add1(i);
    cout << i << endl;
}
```

```cpp
int add1(int &i) {
    return i+1;
}

int main() {
    int i=5;
    i = add1(i);
    cout << i << endl;
}
```

**Review 7.19.** Suppose a function

```cpp
bool f(int);
```

is given, which is true for some positive input value. Write a main program that finds the smallest positive input value for which \(f\) is true.

**Review 7.20.** Suppose a function

```cpp
bool f(int);
```

is given, which is true for some negative input value. Write a code fragment that finds the (negative) input with smallest absolute value for which \(f\) is true.

**Review 7.21.** Suppose a function

```cpp
bool f(int);
```

is given, which computes some property of integers. Write a code fragment that tests if \(f(i)\) is true for
some $0 \leq i < 100$, and if so, prints a message.

**Review 7.22.** Suppose a function

```cpp
bool f(int);
```

is given, which computes some property of integers. Write a main program that tests if $f(i)$ is true for all $0 \leq i < 100$, and if so, prints a message.

### 7.9.1 Eight queens

This problem requires you to know about arrays/vectors; chapter 11.

A famous exercise for recursive programming is the *eight queens* problem: Is it possible to position eight queens on a chessboard, so that they don’t threaten each other?

That is,

- Put eight pieces on an $8 \times 8$ board, no two pieces on the same square; so that
- no two pieces are on the same row,
- no two pieces are on the same column, and
- no two pieces are on the same diagonal.

A systematic solution would run:

1. put a piece anywhere in the first row;
2. for each choice in the first row, try all positions in the second row;
3. for all choices in the first two rows, try all positions in the third row;
4. when you have a piece in all eight rows, evaluate the board to see if it satisfies the condition.

**Exercise 7.23.** This algorithm will generate all $8^8$ boards. Do you see at least one way to speed up the search?

Since the number eight is, for now, fixed, you could write this code as an eight-deep loop nest. However that is not elegant.

**Exercise 7.24.** Solve the eight queens problem recursively, aborting searches optimally early.

Some hints.

- The main program can literally be this short:

```cpp
placement initial(NQUEENS);
auto solution = place_queen(initial);
```
7. Functions

- You may be tempted to write

```c
void place_queen( int row /* more parameters */ ) {
    for (int column=0; column<N; column++)
        // try queen at (row,column)
        // recursive call for row+1
        // erase queen at (row,column) and higher rows
}
```

but this is cumbersome. Instead, for each column, make a copy of the current board, and use
that for the recursive call.

- The basic data structure for this exercise is the $8 \times 8$ board, but that is inefficient. Can you find
  a more compact way of representing the board? Bear in mind that there is only one queen per
  row. Is this optimization important? Argue the time and space demands of the two strategies.
Chapter 8

Scope

8.1 Scope rules

The concept of scope answers the question ‘when is the binding between a name (read: variable) and the internal entity valid’.

8.1.1 Lexical scope

C++, like Fortran and most other modern languages, uses lexical scope rule. This means that you can textually determine what a variable name refers to.

```c
int main() {
    int i;
    if (something) {
        int j;
        // code with i and j
    }
    int k;
    // code with i and k
}
```

- The lexical scope of the variables \( i, k \) is the main program including any blocks in it, such as the conditional, from the point of definition onward. You can think that the variable in memory is created when the program execution reaches that statement, and after that it can be referred to by that name.
- The lexical scope of \( j \) is limited to the true branch of the conditional. The integer quantity is only created if the true branch is executed, and you can refer to it during that execution. After execution leaves the conditional, the name ceases to exist, and so does the integer in memory.
- In general you can say that any use of a name has be in the lexical scope of that variable, and after its definition.

8.1.2 Shadowing

Scope can be limited by an occurrence of a variable by the same name:
8. Scope

The first variable $i$ has lexical scope of the whole program, minus the two conditionals. While its lifetime is the whole program, it is unreachable in places because it is shadowed by the variables $i$ in the conditionals.

This is independent of dynamic / runtime behaviour!

Exercise 8.1. What is the output of this code?

```cpp
bool something(false);
int i = 3;
if ( something ) {
    int i = 5;
    cout << "Local: " << i << endl;
}
cout << "Global: " << i << endl;
if ( something ) {
    float i = 1.2;
    cout << "Local again: " << i << endl;
    cout << "Global again: " << i << endl;
}
```

Exercise 8.2. What is the output of this code?

```cpp
for (int i=0; i<2; i++) {
    int j; cout << j << endl;
    j = 2; cout << j << endl;
}
```

8.1.3 Lifetime versus reachability

The use of functions introduces a complication in the lexical scope story: a variable can be present in memory, but may not be textually accessible:
8.1. Scope rules

```c
void f() {
    ...
}
int main() {
    int i;
    f();
    cout << i;
}
```

During the execution of `f`, the variable `i` is present in memory, and it is unaltered after the execution of `f`, but it is not accessible.

A special case of this is recursion:

```c
void f(int i) {
    int j = i;
    if (i<100)
        f(i+1);
}
```

Now each incarnation of `f` has a local variable `i`; during a recursive call the outer `i` is still alive, but it is inaccessible.

8.1.4 Scope subtleties

8.1.4.1 Mutual recursion

If you have two functions `f, g` that call each other,

```c
int f(int i) { return g(i-1); }
int g(int i) { return f(i+1); }
```

you need a forward declaration

```c
int g(int);
int f(int i) { return g(i-1); }
int g(int i) { return f(i+1); }
```

since the use of name `g` has to come after its declaration.

There is also forward declaration of classes. You can use this if one class contains a pointer to the other:

```c
class B;
class A {
private:
    shared_ptr<B> myB;
};
class B {
private:
    int myint;
}
```

You can also use a forward declaration if one class is an argument or return type:

```c
class B;
class A {
```
8. Scope

```cpp
public:
    B GimmeB();
};
class B {
public:
    B(int);
}
```

However, there is a subtlety here: in the definition of `A` you can not give the full definition of the function that return `B`:

```cpp
class B;
class A {
public:
    B GimmeB() { return B(5); }; // WRONG: does not compile
};
```

because the compiler does not yet know the form of the `B` constructor.

The right way:

```cpp
class B;
class A {
public:
    B GimmeB();
};
class B {
public:
    B(int);
}
B A::GimmeB() { return B(5); }
```

8.1.4.2 Closures

The use of lambdas or closures (section 7.6) comes with another exception to general scope rules. Read about ‘capture’.

8.2 Static variables

Variables in a function have *lexical scope* limited to that function. Normally they also have *dynamic scope* limited to the function execution: after the function finishes they completely disappear. (Class objects have their destructor called.)

There is an exception: a *static variable* persists between function invocations.

```cpp
void fun() {
    static int remember;
}
```

For example
int onemore() {
    static int remember++; return remember;
}
int main() {
    for(...) {
        cout << onemore() << end;
        return 0;
    }
}

gives a stream of integers.

Exercise 8.3. The static variable in the onemore function is never initialized. Can you find a mechanism for doing so? Can you do it with a default argument to the function?

8.3 Scope and memory

The notion of scope is connected to the fact that variables correspond to objects in memory. Memory is only reserved for an entity during the dynamic scope of the entity. This story is clear in simple cases:

int main() {
    // memory reserved for 'i'
    if (true) {
        int i; // now reserving memory for integer i
        ... code ...
    }
    // memory for 'i' is released
}

Recursive functions offer a complication:

int f(int i) {
    int itmp;
    ... code with 'itmp' ...
    if (something)
        return f(i-1);
    else return 1;
}

Now each recursive call of f reserves space for its own incarnation of itmp.

In both of the above cases the variables are said to be on the stack: each next level of scope nesting or recursive function invocation creates new memory space, and that space is released before the enclosing level is released.

Objects behave like variables as described above: their memory is released when they go out of scope. However, in addition, a destructor is called on the object, and on all its contained objects:
8. Scope

Code:

class SomeObject {
  public:
    SomeObject() {
      cout << "calling the constructor"
        << endl;
    }
    ~SomeObject() {
      cout << "calling the destructor"
        << endl;
    }
};

Output
[object] destructor:
Before the nested scope
calling the constructor
Inside the nested scope
calling the destructor
After the nested scope

8.4 Review questions

Review 8.4. Is this a valid program?

```cpp
void f() { i = 1; }
int main() {
    int i=2;
    f();
    return 0;
}
```

If yes, what does it do; if no, why not?

Review 8.5. What is the output of:

```cpp
#include <iostream>
using std::cout;
using std::endl;
int main() {
    int i=5;
    if (true) { i = 6; }
    cout << i << endl;
    return 0;
}
```

Review 8.6. What is the output of:

```cpp
#include <iostream>
using std::cout;
using std::endl;
int main() {
    int i=5;
    if (true) { int i = 6; }
    cout << i << endl;
    return 0;
}
```
Review 8.7. What is the output of:

```cpp
#include <iostream>
using std::cout;
using std::endl;
int main() {
    int i=2;
    i += /* 5; */
    i += /* 6; */
    cout << i << endl;
    return 0;
}
```
8. Scope
Chapter 9

Structures

9.1 Why structures?

You have seen the basic datatypes in section 4.3.4. These are enough to program whatever you want, but it would be nice if the language had some datatypes that are more abstract, closer to the terms in which you think about your application. For instance, if you are programming something to do with geometry, you had rather talk about points than explicitly having to manipulate their coordinates.

Structures are a first way to define your own datatypes\(^1\). A `struct` acts like a datatype for which you choose the name. A `struct` contains other datatypes; these can be elementary, or other structs.

```c
struct Point {
    double x; double y; int label;
};
```

The elements of a structure are also called *members*.

The reason for using structures is to ‘raise the level of abstraction’: instead of talking about \(x, y\)-values, you can now talk about points and such. This makes your code look closer to the application you are modeling.

9.2 The basics of structures

A structure behaves like a data type: you declare variables of the structure type, and you use them in your program. The new aspect is that you first need to define the structure type. This definition can be done inside your main program or before it. The latter is preferable.

```c
// definition of the struct
struct StructName ( int num; double val; )
int main() {
    // declaration of struct variables
    StructName mystruct1, mystruct2;
    .... code that uses your structures ....
}
```

There are various ways of setting the members of the structure:

---

1. Note for instructors: structures in C++ are actually largely the same as classes. This chapter really teaches structures as they appear in C. However, that’s a good first step towards classes.
9. Structures

• You can set defaults that hold for any structure of that type;
• you can all members at once;
• or you can set any member individually.

Struct initialization

You assign a whole struct, or set defaults in the definition.

```c
struct Point_a { double x; double y; };

// initialization when you create the variable:
struct Point_a x_a = {1.5, 2.6};
```

Using structures

Once you have defined a structure, you can make variables of that type. Setting and initializing them takes a new syntax:

```c
int main() {
    struct Point p1, p2;
    p1.x = 1.; p1.y = 2.; p1.label = 5;
    p2 = {3., 4., 5};
    p2 = p1;
    cout << "p2: " << p2.x << "," << p2.y << endl;
}
```

Period syntax: compare to possessive ‘apostrophe-s’ in English.

Review 9.1. True or false?

• All members of a struct have to be of the same type.
• Writing
  ```c
  struct numbered { int n; double x; };
  ```
  creates a structure with an integer and a double as members.
• All members of a struct have to be of different types.
• With the above definition and `struct numbered xn;`,
  ```c
  cout << xn << endl;
  ```
  Is this correct C++?
• With the same definitions, is this correct C++?
  ```c
  xn.x = xn.n+1;
  ```

Exercise 9.2. Define a struct GridPoint that models a grid point, meaning a point with integer coordinates. The Manhattan distance is defined as the sum of (absolute values of) the components. Read the values of the two components, and if the x component is more than the y, print ‘this location is cross-town’, otherwise print ‘this location is uptown’.

108 Introduction to Scientific Programming
9.3 Structures and functions

You can base this off the file gridpoint.cxx.

**Remark 7** Before C++14, if you used initializations in the `struct` definition, you could not use the brace-assignment. This has been fixed.

```cpp
// initialization done in the structure definition:
struct Point_b { double x=0; double y=0; };

struct Point_b x_b;
// legal since 14: ILLEGAL:
x_b = {3.7, 4.8};
// always legal
x_b.x = 3.7; x_b.y = 4.8;
```

## 9.3 Structures and functions

You can use structures with functions, just as you could with elementary datatypes.

### Functions on structures

You can pass a structure to a function:

**Code:**

```cpp
double distance ( struct point p1,
    struct point p2 )
{
    double
d1 = p1.x-p2.x, d2 = p1.y-p2.y;
    return sqrt( d1*d1 + d2*d2 );
}
/* ... */
cout << "dx=" << dx
    << ", dy=" << dy << endl;
stuct point p2 = { p1.x+dx,p1.y+dy };
cout << "Distance: "
    << distance(p1,p2) << endl;
```

**Output**

```cpp```
[struct] pointfun:

```cpp```
dx=5, dy=12
Distance: 13
```

**Exercise 9.3.** Write a point structure, and a function that, given such a point, returns the angle with the x-axis. (Hint: the `atan` function is in `cmath`)

Victor Eijkhout
9. Structures

The mechanisms of parameter passing by value and parameter passing by reference apply to structures just as to simple datatypes.

Exercise 9.4. Write a void function that has a struct Point parameter, and exchanges its coordinates:

\[
\begin{pmatrix} 2.5 \\ 3.5 \end{pmatrix} \rightarrow \begin{pmatrix} 3.5 \\ 2.5 \end{pmatrix}
\]

Exercise 9.5. Write a function \( y = f(x, a) \) that takes a struct Point and double parameter as input, and returns a point that is the input multiplied by the scalar.

\[
\begin{pmatrix} 2.5 \\ 3.5 \end{pmatrix}, 3 \rightarrow \begin{pmatrix} 7.5 \\ 10.5 \end{pmatrix}
\]

Exercise 9.6. If you are doing the prime project (chapter 52) you can now do exercise 52.8.

Exercise 9.7. Write a function inner_product that takes two Point structures and computes the inner product. Test your code on some points where you know the answer.
For a more sophisticated version of this exercise:

**Exercise 9.8.** Write two functions:
1. `rotate` takes a point \( v \) and a scalar \( \alpha \) and returns a point that is \( v \) rotated over \( \alpha \).
2. `inner_product` that takes two points and returns their inner product.

Now apply the inner product function on a point \( v \) and \( v \) rotated by \( \pi / 2 \). Is their inner product zero?

Here you can learn about floating point arithmetic and floating point error.

Now write a boolean function `is_orthogonal` that works in the presence of floating point error.

**Denotations**
You can use initializer lists as struct denotations
(with the `distance` function previously defined):

```
struct point p1{1.,2.}, p2{6.,14.};
cout << "Distance: "
    << distance( p1,p2 )
    << endl;
cout << "Distance: "
    << distance( {1.,2.},{6.,14.} )
    << endl;
```

**Exercise 9.9.** Take exercise 9.7 and rewrite it to use denotations.

**Returning structures**
You can return a structure from a function:

```
struct point point_add( struct point p1,
                         struct point p2 )
{struct point p_add =
  {p1.x+p2.x,p1.y+p2.y};
  return p_add;
};

v3 = point_add(p1,p2);
cout << "Added: "
    << v3.x << "," << v3.y << endl;
```

(In case you’re wondering about scopes and lifetimes here: the explanation is that the returned value is copied.)
Exercise 9.10. Write a $2 \times 2$ matrix class (that is, a structure storing 4 real numbers), and write a function \textit{multiply} that multiplies a matrix times a vector.

Can you make a matrix structure that is based on the vector structure (essentially the same as a \textit{Point} struct), for instance using vectors to store the matrix rows, and then using the inner product method to multiply matrices?
Chapter 10

Classes and objects

10.1 What is an object?

You learned about structures (chapter 9) as a way of abstracting from the elementary data types. The elements of a structure were called its members.

You also saw that it is possible to write functions that work on structures. We now combine these two elements to give a new level of abstraction: an object belonging to a class.

- An object is an entity that you can request to do certain things. These actions are the methods and to make these possible the object probably stores data, the members.
- When designing a class, first ask yourself: ’what functionality should the objects support’.
- Objects comes in classes. A class is like a datatype: you can make objects of a class like variables of a datatype.
- Objects of the same class have the same methods. They also have the same members, but with individual values.

Objects belong to a class, so, as with structures:
- You need a class definition, typically placed before the main program.
- (In larger programs you would put it in a include file.)
- You can then declare multiple objects belonging to that class.
- Objects can then be used in expressions, passed as parameter, et cetera.

Let’s look at a simple example: as with structures we want a Point object, corresponding to a mathematical point in $\mathbb{R}^2$. Given a point, you could want to know its distance to the origin or its angle with the $x$-axis.

Object functionality

Small illustration: vector objects.

```
Point p(1.,2.); // make point (1,2)
cout << "distance to origin " << p.distance_to_origin() << endl;
p.scaleby(2.);
cout << "distance to origin " << p.distance_to_origin() << endl
   << "and angle " << p.angle() << endl;
```

Output

[object] functionality:

distance to origin 2.23607
distance to origin 4.47214
and angle 1.10715
Note the ‘dot’ notation; in a `struct` we use it for the data members; in an object we (also) use it for methods.

Exercise 10.1. Thought exercise:
What data does the object need to store to do this?
Is there more than one possibility?

The object workflow

Similar to `struct`:
- You have to define what an object looks like by giving a
  ```
  class myobject { /* ... */ };
  ```
  definition, typically before the `main`
- You create specific objects with a declaration
  ```
  myobject
  object1( /* .. */ ),
  object2( /* .. */ );
  ```
- You let the objects do things:
  ```
  object1.do_this();
  x = object2.do_that( /* ... */ );
  ```

10.1.1 Constructor

Next we’ll look at a syntax for creating class objects that is new. If you create an object, you actually call a function that has the same name as the class: the constructor.

Usually you write your own constructor, for instance to initialize data members. This fragment of the `class Point` shows the constructor and the data members:

```
class Point {
  private: // members
  double x,y;
  public: // methods, first the constructor:
  Point( double x_in, double y_in ) {
    x = x_in; y = y_in; }
  /* ... */
};
```

As you see, the function of the constructor is to take the coordinates of the point and to copy them to private members of the `Point` object.

Member initialization in the constructor

The members stored can be different from the constructor arguments.

Example: create a vector from `x,y` cartesian coordinates, but store `r,theta` polar coordinates:

```
#include <cmath>
class Point {
  private: // members
  double r,theta;
};
```
10.1. What is an object?

Constructor and initialization

- Keyword `private` indicates that data is internal
- Keyword `public` indicates that the constructor function can be used in the program.

10.1.2 Methods, introduction

Methods are things you can ask your class objects to do. For instance, in the `Point` class, you could ask what its distance is to the origin, or you could ask it to scale its distance by some number.

**Class methods**

Let’s define method `distance`.

**Definition in the class:**

```cpp
def double distance_to_origin() {
  return sqrt(x*x + y*y);
}
```

**Use in the program:**

```cpp
Point pt(5,12);
double s = pt.distance_to_origin();
```

- Methods look like ordinary functions,
- except that they can use the data members of the class, for instance `x`;
- Methods can only be used on an object with the ‘dot’ notation. They are not independently defined.

**Code:**

```cpp
class Point {
  private:
    float x,y;
  public:
    Point(float ux,float uy) { x = ux; y = uy; }
    float distance_to_origin() {
      return sqrt( x*x + y*y );
    }
};
```

**Output**

[geom] pointodist:

Distance to origin: 1.41421

Exercise 10.2. Add a method `angle` to the `Point` class. How many parameters does it need?

**Hint:** use the function `atan` or `atan2`.

**You can base this off the file pointclass.cxx.cxx.**
Exercise 10.3. Make a class `GridPoint` which can have only integer coordinates. Implement a function `manhattan_distance` which gives the distance to the origin counting how many steps horizontal plus vertical it takes to reach that point.

### 10. Classes and objects

#### 10.1.3 Initialization

**Member default values**

Class members can have default values, just like ordinary variables:

```cpp
class Point {
private:
    float x=3., y=.14;
private:
    // et cetera
}
```

Each object will have its members initialized to these values.

In section 10.1.1 you saw how the constructor can be used to set the private members of an object.

**Member initializer lists**

Other syntax for initialization: use initializer list.

```cpp
class Point {
private:
    double x,y;
public:
    Point( double userx, double usery ) :
        x(userx), y(usery) {}
}
```

**Advantage of initializer list**

Allows for reuse of names:

```cpp
class Vector {
private:
    double x,y;
public:
    Vector( double x, double y ) : x(x), y(y) {}
    /* ... */
    Vector p1(1.,2.);
    cout << "p1 = " << p1.getx() << "," << p1.gety() << endl;
}
```

Also saves on constructor invocation if the member is an object.
The initialization $x(x)$ is a member initializer list; it should be read as $membername(argumentname)$. Yes, having $x$ twice is a little confusing.

**Remark 8** The order of the member initializer list is ignored: the members specified will be initialized in the order in which they are declared. There are cases where this distinction matters, so best put both in the same order.

**Initializer lists**

Initializer lists can be used as denotations.

```cpp
Point(float ux, float uy) {
    /* ... */
}
Rectangle(Point bl, Point tr) {
    /* ... */
}
Point origin(0., 0.);
Rectangle lielow( origin, {5,2} );
```

**10.1.4 Methods**

You have just seen examples of class methods: a function that is only defined for objects of that class, and that has access to the private data of that object.

**Exercise 10.4.** Discuss the pros and cons of this design:

```cpp
class Point {
    private: // members
        double x, y;
    public: // methods, first the constructor:
        Point(double in_x, double in_y) : x(in_x), y(in_y) {}
        /* ... */
};

double angle() { return alpha; }
```

By making these functions public, and the data members private, you define an Application Programmer Interface (API) for the class:

- You are defining operations for that class; they are the only way to access the data of the object.
- The methods can use the data of the object, or alter it. All data members, even when declared `private`, are global to the methods.
10. Classes and objects

- Data members declared private are not accessible from outside the object.

**Review 10.5. T/F?**
- A class is primarily determined by the data it stores.
- A class is primarily determining by its methods.
- If you change the design of the class data, you need to change the constructor call.

### 10.1.4.1 Changing state

Objects usually have data members that maintain the state of the object. By changing the values of the members you change the state of the object. Doing so is usually done through a method.

#### Methods that alter the object

For instance, you may want to scale a vector by some amount:

**Code:**

```cpp
class Point {
    /* ... */
    void scaleby(double a) {
        vx *= a; vy *= a; }
    /* ... */
};
/* ... */
Point p1(1.,2.);
cout << "p1 to origin " << p1.length() << endl;
p1.scaleby(2.);
cout << "p1 to origin " << p1.length() << endl;
```

**Output**

```
[geom] pointscaleby:
p1 to origin 2.23607
p1 to origin 4.47214
```

**Exercise 10.6.** Implement a method `shift_right` for the `Point` class.

### 10.1.4.2 Methods that return objects

The methods you have seen so far only returned elementary datatypes. It is also possible to return an object, even from the same class. For instance, instead of scaling the members of a vector object, you could create a new object based on the scaled members:
10.1. What is an object?

Code:
```cpp
class Point {
    /* ... */
    Point scale(double a);
    /* ... */

    cout << "p1 to origin 
    << p1.length() << endl;
    Point p2 = p1.scale(2.);
    cout << "p2 to origin 
    << p2.length() << endl;
};
```

Output
```
[geom] pointscale:
p1 to origin 2.23607
p2 to origin 4.47214
```

Anonymous objects

Two ways of returning the scaled point:

Naive:
```cpp
Point Point::scale(double a) {
    Point scaledpoint = Point(x*a, y*a);
    return scaledpoint;
};
```

No copy involved:
```cpp
Point Point::scale(double a) {
    return Point(x*a, y*a);
};
```

10.1.5 Default constructor

So far you’ve seen class and their constructors. A class with no constructor defined by you still has a default constructor. For example:

```cpp
class IamZero {
    private:
        int i = 0;
    public:
        void print() { cout << i; }
};
```

You recognize the default constructor by the fact that an object is defined without any parameters.

```cpp
IamZero zero;
zero.print();
```

Such a class acts like it has a constructor

```cpp
IamZero() {};
```

Bear this in mind as you study the following code:

```cpp
Point p1(1., 2.), p2;
cout << "p1 to origin " << p1.length() << endl;
p2 = p1.scale(2.);
cout << "p2 to origin " << p2.length() << endl;
```

With the Point class (and its constructor) as given above, this will give an error message during compilation. The reason is that

```cpp
Point p2;
```

calls the default constructor. Now that you have defined your own constructor, the default constructor no longer exists. So you need to define it explicitly:
10. Classes and objects

```cpp
Point() {};
Point( double x, double y )
    : x(x), y(y) {};
```

You now have a class with two constructors. The compiler will figure out which one to use. This is an example of polymorphism.

**Remark 9** The default constructor has ‘empty parentheses’, but you use it specifying no parentheses. What would happen if you specified empty parentheses when you create an object?

```cpp
class MyClass {
public:
    MyClass() { cout << "Construct!" << endl; };
};

int main() {
    MyClass x;
    MyClass y();
}
```

```
constructparen.cxx:24:12: warning:
empty parentheses interpreted as a function declaration
    MyClass y();
constructparen.cxx:24:12: note:
remove parentheses to declare a variable
    MyClass y();
1 warning generated.
```

10.1.6 Accessors

You may have noticed the keywords `public` and `private`. We made the data members private, and the methods public. Thinking back to structures, you could say that their data members were (by default) public. Why don’t we do that here?

**Struct data is public:**

```cpp
struct Point {
    double x;
};

int main() {
    Point andhalf;
    andhalf.x = 1.5;
}
```

**Class Point:**

```cpp
class Point {
public: // Bad! Idea!
    double x;
};

int main() {
    Point andhalf;
    andhalf.x = 2.6;
}
```

Objects are really supposed to be accessed through their functionality. While you could write methods such as `get_x`, (this is called an accessor) to get the $x$ coordinate, ask yourself if that makes sense. If you need the $x$ coordinate to shift the point rightward, write a `shift_right` method instead.

```
struct Point {
    double x;
};
```

```
class Point {
public: // Bad! Idea!
    double x;
};
```

```
struct Point {
    double x;
};
```

```
class Point {
public: // Bad! Idea!
    double x;
};
```
10.1. What is an object?

**Public versus private**

- Interface: `public` functions that determine the functionality of the object; effect on data members is secondary.
- Implementation: data members, keep `private`: they only support the functionality.

This separation is a Good Thing:

- Protect yourself against inadvertant changes of object data.
- Possible to change implementation without rewriting calling code.

You should not write access functions lightly: you should first think about what elements of your class should conceptually be inspectable or changeable by the outside world. Consider for example a class where a certain relation holds between members. In that case only changes are allowed that maintain that relation.

**Access gone wrong**

We make a class for points on the unit circle.

You don’t want to be able to change just one of $x,y$!

```cpp
class UnitCirclePoint {
private:
    float x, y;
public:
    UnitCirclePoint(float x) {
        setx(x); }
    void setx(float newx) {
        x = newx; y = sqrt(1-x*x); }
};
```

In general: enforce predicates on the members.

10.1.7 Examples

**Classes for abstract objects**

Objects can model fairly abstract things:
10. Classes and objects

Code:

```cpp
class Stream {
private:
  int last_result = 0;
public:
  int next() {
    return last_result++; }
};

int main() {
  Stream ints;
  cout << "Next: " << ints.next() << endl;
  cout << "Next: " << ints.next() << endl;
  cout << "Next: " << ints.next() << endl;
}
```

Output

[object] stream:
Next: 0
Next: 1
Next: 2

Exercise 10.7.
- Write a class `multiples_of_two` where every call of `next` yields the next multiple of two.
- Write a class `multiples` used as follows:
  ```cpp
  multiples multiples_of_three(3);
  ```
  where the `next` call gives the next multiple of the argument of the constructor.

You can base this off the file `stream.cxx`. cxx

Exercise 10.8. If you are doing the prime project (chapter 52), now is a good time to do exercise 52.9.

10.2 Inclusion relations between classes

The data members of an object can be of elementary datatypes, or they can be objects. For instance, if you write software to manage courses, each `Course` object will likely have a `Person` object, corresponding to the teacher.

```cpp
class Person {
  string name;
  ...
};
class Course {
  private:
    int year;
    Person the_instructor;
    vector<Person> students;
};
```

Designing objects with relations between them is a great mechanism for writing structured code, as it makes the objects in code behave like objects in the real world. The relation where one object contains another, is called a has-a relation between classes.
10.2. Inclusion relations between classes

10.2.1 Literal and figurative has-a

Sometimes a class can behave as if it includes an object of another class, while not actually doing so. For instance, a line segment can be defined from two points

```cpp
class Segment {
    private:
        Point starting_point, ending_point;
    }

int main() {
    Segment somesegment;
    Point somepoint = somesegment.get_the_end_point();
}
```

or from one point, and a distance and angle:

```cpp
class Segment {
    private:
        Point starting_point;
        float length, angle;
    }
```

In both cases the code using the object is written as if the segment object contains two points. This illustrates how object-oriented programming can decouple the API of classes from their actual implementation.

Related to this decoupling, a class can also have two very different constructors.

**Multiple constructors**

```cpp
class Segment {
    private:
        // up to you how to implement!
    public:
        Segment( Point start, float length, float angle )
        { .... }
        Segment( Point start, Point end ) { ... }
}
```

Depending on how you actually implement the class, the one constructor will simply store the defining data, and the other will do some conversion from the given data to the actually stored data.

This is another strength of object-oriented programming: you can change your mind about the implementation of a class without having to change the program that uses the class.

When you have a has-a relation between classes, the ‘default constructor’ problem (section 10.1.5) can pop up again:

**Default Constructors in initialization**

```cpp
class Inner { /* ... */ };
class Outer {
    private:
        Inner inside_thing;
}
```

Two possibilities for constructor:
10. Classes and objects

The Inner object is copied during construction of the Outer object. The Outer object is created, including construction of Inner object, then the argument is copied into place; ⇒ needs default constructor on Inner.

Exercise 10.9. If you are doing the geometry project, this is a good time to do the exercises in section 53.3.

10.3 Inheritance

In addition to the has-a relation, there is the is-a relation, also called inheritance. Here one class is a special case of another class. Typically the object of the derived class (the special case) then also inherits the data and methods of the base class (the general case).

**Examples for base and derived cases**

- Base case: employee. Has: salary, employee number.
  Special case: manager. Has in addition: underlings.
- Base case: shape in drawing program. Has: extent, area, drawing routine.
  Special case: square et cetera; has specific drawing routine.

```cpp
class General {
    protected: // note!
    int g;
public:
    void general_method() {};
};
class Special : public General {
public:
    void special_method() { ... g ... };
};
```

How do you define a derived class?

- You need to indicate what the base class is:
  ```cpp
  class Special : public General { .... }
  ```
- The base class needs to declare its data members as `protected`: this is similar to private, except that they are visible to derived classes
- The methods of the derived class can then refer to data of the base class;
- Any method defined for the base class is available as a method for a derived class object.

The derived class has its own constructor, with the same name as the class name, but when it is invoked, it also calls the constructor of the base class. This can be the default constructor, but often you want to call the base constructor explicitly, with parameters that are describing how the special case relates to the base case. Example:
class General {
public:
    General( double x, double y ) {};
};
class Special : public General {
public:
    Special( double x ) : General(x, x+1) {};
};

### Access levels

Methods and data can be

- private, because they are only used internally;
- public, because they should be usable from outside a class object, for instance in the main program;
- protected, because they should be usable in derived classes.

### Exercise 10.10

If you are doing the geometry project, you can now do the exercises in section 53.4.

### 10.3.1 Methods of base and derived classes

#### Overriding methods

- A derived class can inherit a method from the base class.
- A derived class can define a method that the base class does not have.
- A derived class can **override** a base class method:

```cpp
class Base {
    public:
        virtual f() { ... };
};
class Deriv : public Base {
    public:
        virtual f() override { ... };
};
```

#### Override and base method
10. Classes and objects

Code:

```cpp
class Base {
protected:
    int i;
public:
    Base(int i) : i(i) {}
    virtual int value() { return i; }
};
class Deriv : public Base {
public:
    Deriv(int i) : Base(i) {}
    virtual int value() override {
        int ivalue = Base::value();
        return ivalue * ivalue;
    }
};
```

Output

```text
[object] virtual:
25
```

10.3.2 Virtual methods

Base vs derived methods

- Method defined in base class: can be used in any derived class.
- Method defined in derived class: can only be used in that particular derived class.
- Method defined both in base and derived class, marked override: derived class method replaces (or extends) base class method.
- Virtual method: base class only declares that a routine has to exist, but does not give base implementation.

A class is called abstract class if it has virtual methods; pure virtual if all methods are virtual. You can not make abstract objects.

Abstract classes

Special syntax for abstract method:

```cpp
class Base {
public:
    virtual void f() = 0;
};
class Deriv : public Base {
public:
    virtual void f() { ... };
};
```

Example: using virtual class

```cpp
class VirtualVector {
private:
public:
    virtual void setlinear(float) = 0;
    virtual float operator[](int) = 0;
};
```

Suppose DenseVector derives from VirtualVector:

```cpp
DenseVector v(5);
v.setlinear(7.2);
cout << v[3] << endl;
```
10.3. Inheritance

Implementation

```cpp
class DenseVector : VirtualVector {
private:
    vector<float> values;
public:
    DenseVector(int size) {
        values = vector<float>(size, 0);
    }
    void setlinear(float v) {
        for (int i=0; i<values.size(); i++)
            values[i] = i*v;
    }
    float operator[](int i) {
        return values.at(i);
    }
};
```

Exercise 10.11. Advanced! Write a small “integrator” library for Ordinary Differential Equations (ODEs). Assuming ‘autonomous ODEs’, that is $u' = f(t)$ with no $u$-dependence, there are two simple integration schemes:

- explicit: $u_{n+1} = u_n + \Delta t f_n$; and
- implicit: $u_{n+1} = u_n + \Delta t f_{n+1}$.

Write an abstract Integrator class where the nextstep method is pure virtual; then write ExplicitIntegrator and ImplicitIntegrator classes deriving from this.

```cpp
double stepsize = .01;
auto integrate_linear = 
    ForwardIntegrator([] (double x) { return x*x; }, stepsize);
double int1 = integrate_linear.to(1.);
```

You can hardcode the function to be integrated, or try to pass a function pointer.

10.3.3 Friend classes

Friend classes

A friend class can access private data and methods even if there is no inheritance relationship.

```cpp
class A {
    friend class B;
}
```

10.3.4 Multiple inheritance
10. Classes and objects

More

- Multiple inheritance: an X is-a A, but also is-a B. This mechanism is somewhat dangerous.
- Virtual base class: you don’t actually define a function in the base class, you only say ‘any derived class has to define this function’.

Exercise 10.12. This is a good time to do the exercises in section 53.2.

10.4 Advanced topics

The remainder of this section is advanced material. Make sure you have studied section 15.3.

10.4.1 Class prototypes

For purposes of organizing your code, you may sometimes not want to include the full code of a method in the class definition. It is in fact possible to write a class definition, giving only the prototype of a class method, and specify the full method later or elsewhere.

```cpp
class Point {
private:
  float x, y;
public:
  Point(float x, float y);
  float distance();
};

Point::Point() : x(x), y(y) {};
float Point::distance() {
  return sqrt(x*x + y*y);
};
```

- Methods, including constructors, are only given by their function header in the class definition.
- Methods and constructors are then given their full definition elsewhere with ‘classname-double-colon-methodname’ as their name.
- (qualifiers like const are given in both places.)

10.4.2 Returning by reference

Direct alteration of internals

Return a reference to a private member:

```cpp
class Point {
private:
  double x, y;
public:
  double &x_component() { return x; };
};
int main() {
  Point v;
  v.x_component() = 3.1;
}
```
Only define this if really needed.

Reference to internals

Returning a reference saves you on copying.
Prevent unwanted changes by using a ‘const reference’.

```cpp
class Grid {
private:
    vector<Point> thepoints;
public:
    const vector<Point> &points() {
        return thepoints;
    }
};

int main() {
    Grid grid;
    cout << grid.points()[0];
    // grid.points()[0] = whatever ILLEGAL
}
```

10.4.3 Accessor functions

It is a good idea to make the data in an object private, to control outside access to it.

- Sometimes this private data is auxiliary, and there is no reason for outside access.
- Sometimes you do want outside access, but you want to precisely control by whom.

Accessor functions:

```cpp
class thing {
private:
    float x;
public:
    float get_x() { return x; };
    void set_x(float v) { x = v; }
};
```

This has advantages:

- You can print out any time you get/set the value; great for debugging:

  ```cpp
  void set_x(float v) {
      cout << "setting: " << v << endl;
      x = v;
  }
  ```

- You can catch specific values: if $x$ is always supposed to be positive, print an error (throw an exception) if nonpositive.

Having two accessors can be a little clumsy. Is it possible to use the same accessor for getting and setting?

Setting members through accessor

Use a single accessor for getting and setting:
10. Classes and objects

Code:

```cpp
class SomeObject {
private:
  float x = 0.;
public:
  SomeObject(float v) : x(v) {};
  float &xvalue() { return x; };
};

int main() {
  SomeObject myobject(1.);
  cout << "Object member initially :" << myobject.xvalue() << endl;
  myobject.xvalue() = 3.;
  cout << "Object member updated :" << myobject.xvalue() << endl;
}
```

Output

```
[object] accessref:
Object member initially :1
Object member updated :3
```

The function `xvalue` returns a reference to the internal variable `x`.

Of course you should only do this if you want the internal variable to be directly changable!

10.4.4 Accessability

Access levels

Methods and data can be
- private, because they are only used internally;
- public, because they should be usable from outside a class object, for instance in the main program;
- protected, because they should be usable in derived classes.

10.4.5 Polymorphism

You can have multiple methods with the same name, as long as they can be distinguished by their argument types. This is known as polymorphism.

10.4.6 Operator overloading

Instead of writing

```cpp
myobject.plus(anotherobject)
```

you can actually redefine the `+` operator so that

```cpp
myobject + anotherobject
```

is legal. This is known as operator overloading.

The syntax for this is

**Operator overloading**

```cpp
<returntype> operator<op>( <argument> ) { <definition> }
```
10.4. Advanced topics

For instance:

**Code:**

```cpp
Point operator*(double factor) {
    return Point(factor*x, factor*y);
};
/* ... */
cout << "p1 to origin "
    << p1.length() << endl;
Point scale2r = p1*2.;
cout << "scaled right: "
    << scale2r.length() << endl;
// ILLEGAL Point scale2l = 2.*p1;
```

**Output**

[geom] pointmult:

```
p1 to origin 2.23607
scaled right: 4.47214
```

Can even redefine equals and parentheses.

**Exercise 10.13.** Write a `Fraction` class, and define the arithmetic operators on it.

### 10.4.7 Functors

A special case of operator overloading is **overloading the parentheses**. This makes an object look like a function; we call this a **functor**.

Simple example:

**Code:**

```cpp
class IntPrintFunctor {
public:
    void operator()(int x) {
        cout << x << endl;
    }
};
/* ... */
IntPrintFunctor intprint;
intprint(5);
```

**Output**

[object] functor:

```
5
```

**Exercise 10.14.** Extend that class as follows: instead of printing the argument directly, it should print it multiplied by a scalar. That scalar should be set in the constructor. Make the following code work:

**Code:**

```cpp
IntPrintTimes printx2(2);
printx2(1);
for ( auto i : {5,6,7,8} )
    printx2(i);
```

**Output**

[object] functor2:

```
2
10
12
14
16
```

(The **for_each** is part of **algorithm**.)
10. Classes and objects

10.4.8 Copy constructor

Just like the default constructor which is defined if you don’t define an explicit constructor, there is an implicitly defined copy constructor. This constructor is invoked whenever you do an obvious copy:

\[
\begin{align*}
\text{my_object } x, y; & \quad // \text{ regular or default constructor} \\
x = y; & \quad // \text{ copy constructor}
\end{align*}
\]

Usually the copy constructor that is implicitly defined does the right thing: it copies all data members. (If you want to define your own copy constructor, you need to know its prototype. We will not go into that.)

Example of the copy constructor in action:

```cpp
class has_int {
private:
    int mine{1};
public:
    has_int(int v) {
        cout << "set: " << v << endl;
        mine = v;
    }
    has_int(has_int &h) {
        auto v = h.mine;
        cout << "copy: " << v << endl;
        mine = v;
    }
    void printme() {
        cout << "I have: " << mine << endl;
    }
};

Code:

has_int an_int(5);
has_int other_int(an_int);
an_int.printme();
other_int.printme();
```

Output

[object] copyscalar:
set: 5
copy: 5
I have: 5
I have: 5

Copying is recursive

Class with a vector:

```cpp
class has_vector {
private:
    vector<int> myvector;
public:
    has_vector(int v) { myvector.push_back(v); }
    void set(int v) { myvector.at(0) = v; }
    void printme() {
        cout << "I have: " << myvector.at(0) << endl;
    }
};
```

Copying is recursive, so the copy has its own vector:
10.4. Advanced topics

Code:
```cpp
has_vector a_vector(5);
has_vector other_vector(a_vector);
a_vector.set(3);
a_vector.printme();
other_vector.printme();
```

Output

[object] copyvector:
I have: 3
I have: 5

10.4.9 Destructor

Just as there is a constructor routine to create an object, there is a destructor to destroy the object. As with the case of the default constructor, there is a default destructor, which you can replace with your own.

A destructor can be useful if your object contains dynamically created data: you want to use the destructor to dispose of that dynamic data to prevent a memory leak. Another example is closing files for which the file handle is stored in the object.

The destructor is typically called without you noticing it. For instance, any statically created object is destroyed when the control flow leaves its scope.

Example:

Code:
```cpp
class SomeObject {
public:
    SomeObject() {
        cout << "calling the constructor"
             << endl;
    }
    ~SomeObject() {
        cout << "calling the destructor"
             << endl;
    }
};
```

Output

[object] destructor:
Before the nested scope
calling the constructor
Inside the nested scope
calling the destructor
After the nested scope

Exercise 10.15. Write a class

```cpp
class HasInt {
private:
    int mydata;
public:
    HasInt(int v) { /* initialize */ };
    ...
}
```

used as
10. Classes and objects

```
class SomeObject {
public:
    SomeObject() {
        cout << "calling the constructor" << endl; 
    };
    "SomeObject() {
        cout << "calling the destructor" << endl; 
    }; 
*/ ... */
try {
    SomeObject obj;
    cout << "Inside the nested scope" << endl;
    throw(1);
} catch (...) {
    cout << "Exception caught" << endl;
}
```

Output

```
[object] exceptdestructor:
calling the constructor
Inside the nested scope
calling the destructor
Exception caught
```

Destructors and exceptions

The destructor is called when you throw an exception:

```
class SomeObject {
public:
    SomeObject() {
        HasInt v(5);
        v.set(6);
        v.set(-2);
    }
```

Output

```
[object] destructexercise:
**** object created with 5 ****
**** object set to 6 ****
**** object set to -2 ****
**** object destroyed after 2 updates ****
```

10.4.10 ‘this’ pointer

‘this’ pointer to the current object

Inside an object, a pointer to the object is available as `this`:

```
class Myclass {
private:
    int myint;
public:
    Myclass(int myint) {
        this->myint = myint; // 'this' redundant!
    }
};
```

‘this’ use

You don’t often need the `this` pointer. Example: you need to call a function inside a method that needs the object as argument)

```
/* forward definition: */
class someclass;
void somefunction(const someclass &c) {
    /* ... */
}
```
10.4. Advanced topics

(Rare use of dereference star)

There is another interesting idiom that uses the ‘this’ pointer. Define a simple class

```cpp
class number {
private:
    float x;
public:
    number(float x) : x(x) {};
    float value() { return x; };
}
```

Defining a method

```cpp
number addcopy(float y) {
    x += y;
    return *this;
}
```

both alters the object, and returns a copy.

Changing the method to return a reference:

```cpp
number& add(float y) {
    x += y;
    return *this;
}
```

```cpp
number& multiply(float y) {
    x *= y;
    return *this;
}
```

has the interesting effect that no copy is created, but the returned ‘object’ is the object itself, by reference. This makes an interesting idiom possible:

```cpp
Code:
number mynumber(1.0);
mynumber.add(.5);
cout << mynumber.value() << endl;
mynumber.multiply(2.).add(1.).multiply(3.);
cout << mynumber.value() << endl;
```

### 10.4.11 Static members

#### Static class members

A static member acts as if it’s shared between all objects.
(Note: C++17 syntax)
10. Classes and objects

Code:

```cpp
class myclass {
private:
    static inline int count = 0;
public:
    myclass() { count++; }
    int create_count() { return count; }
};
/* ... */
myclass obj1, obj2;
out << "I have defined "
    << obj1.create_count()
    << " objects" << endl;
```

Output

```
I have defined 2 objects
```

Static class members, C++11 syntax

```cpp
class myclass {
private:
    static int count;
public:
    myclass() { count++; }
    int create_count() { return count; }
};
/* ... */
// in main program
int myclass::count = 0;
```

10.5 Review question

**Review 10.16.** Fill in the missing term

- The functionality of a class is determined by its...
- The state of an object is determined by its...

How many constructors do you need to specify in a class definition?

- Zero
- Zero or more
- One
- One or more

**Review 10.17.** Describe various ways to initialize the members of an object.
Chapter 11

Arrays

An array is an indexed data structure that for each index stores an integer, floating point number, character, object, et cetera. In scientific applications, arrays often correspond to vectors and matrices, potentially of quite large size. (If you know about the Finite Element Method (FEM), you know that vectors can have sizes in the millions or beyond.)

In this chapter you will see the C++ vector construct, which implements the notion of an array of things, whether they be numbers, strings, objects.

C difference: While C++ can use the C mechanisms for arrays, for almost all purposes it is better to use vector. In particular, this is a safer way to do dynamic allocation. The old mechanisms are briefly discussed in section 11.8.2.

11.1 Some simple examples

11.1.1 Vector creation

To use vectors, you first need the vector header from the Standard Template Library (STL). This allows you to declare a vector, specifying what type of element it contains. Next you may want to decide how many elements it contains; you can specify this when you declare the vector, or determine it later, dynamically.

Short vectors

Short vectors can be created by enumerating their elements:

```cpp
#include <vector>
using std::vector;

int main() {
    vector<int> evens{0, 2, 4, 6, 8};
    vector<float> halves = {0.5, 1.5, 2.5};
    cout << evens.at(0) << endl;
    return 0;
}
```

1. The term ‘array’ is used informally here. There is an array keyword, which is briefly discussed in section 11.8.4.
Exercise 11.1.
1. Take the above snippet, supply the missing header lines, compile, run.
2. Add a statement that alters the value of a vector element. Check that it does what you think it does.
3. Add a vector of the same length, containing odd numbers, which are the even values plus 1?
   *You can base this off the file shortvector.cxx.*

A more sophisticated example:

```cpp
vector<Point> diagonal =
{ {0.,0.}, {1.,1.}, {1.5,1.5}, {2.,2.}, {3.,3.} };
```

11.1.2 Initialization

There are various ways to declare a vector, and possibly initialize it.

More generally, vectors can be defined

- Without further specification, creating an empty vector:
  ```cpp
  vector<float> some_numbers;
  ```

- With a size indicated, allocating that number of elements:
  ```cpp
  vector<float> five_numbers(5);
  ```

**Vector constant initialization**

There is a syntax for initializing a vector with a constant:

```cpp
vector<float> x(25,3.15);
```

which defines a vector $x$ of size 25, with all elements initialized to 3.15.

If your vector is short enough, you can set all elements explicitly with an *initializer list*, and note that the size is not specified here, but is deduced from the length of the initializer list:

```cpp
Code:
```{language=c++}
{ 
  vector<int> numbers={5,6,7,8,9,10};
  cout << numbers.at(3) << endl;
}

{ 
  vector<int> numbers = {5,6,7,8,9,10};
  numbers.at(3) = 21;
  cout << numbers.at(3) << endl;
}
```

Output

[array] dynamicinit:

| 8 |
| 21 |

Review 11.2. T/F?

- It is possible to write a valid C++ program where you define a variable `vector`.  

Introduction to Scientific Programming
11.1.3 Element access

There are two ways of accessing vector elements.

1. With the ‘dot’ notation that you know from structures and objects, you can use the \texttt{at} method:

\begin{verbatim}
vector<int> numbers = \{1,4\};
numbers.at(0) += 3;
numbers.at(1) = 8;
cout << numbers.at(0) << "," << numbers.at(1) << endl;
\end{verbatim}

\textbf{Output} \[\text{assignatfun:} \] 4, 8

2. There is also a short-hand notation (which is the same as in C):

\begin{verbatim}
vector<int> numbers = \{1,4\};
numbers[0] += 3;
numbers[1] = 8;
cout << numbers[0] << "," << numbers[1] << endl;
\end{verbatim}

\textbf{Output} \[\text{assignbracket:} \] 4, 8

Indexing starts at zero. Consequently, a vector declared as

\begin{verbatim}
\texttt{|} vector\texttt{<int>|} \texttt{ints(N)}
\end{verbatim}

As you see in this example, if \texttt{a} is a vector, and \texttt{i} an integer, then \texttt{a.at(i)} is the \texttt{i}’\texttt{th} element.

- The expression \texttt{a.at(i)} can be used to get the value of a vector element, or it can occur in the left-hand side of an assignment to set the value.
- The same holds for indexing with square brackets.
- The \textit{array index} (or \textit{array subscript}) \texttt{i} starts numbering at zero.
- Therefore, if a vector has \texttt{n} elements, its last element has index \texttt{n-1}.

11.1.4 Access out of bounds

Have you wondered what happens if you access an array element outside the bounds of the vector?

\begin{verbatim}
vector<float> x(6); // size 6, index ranges 0..5
x.at(6) = 5.; // oops!
i = -2;
x[i] = 3; // very much oops!
\end{verbatim}

Accessing an element outside the array bounds is hard to detect at compile time. Most likely, it will only be detected at runtime. There is now a difference in how the two accessing methods do \textit{array bounds checking}.

1. Using the \texttt{at} method will always do a bounds test, and exit your program immediately if you access an element outside the array bounds. (Technically, it throws an \textit{exception}; see section \ref{sec:exceptions} for how this works and how you can handle this.)

2. The bracket notation \texttt{a[i]} performs no bounds tests; it calculates a memory address based on the array location and the index, and attempts to return what is there. As you may imagine, this lack of checking makes your code a little faster. However, the lack of makes your code unsafe:
11. Arrays

- Your program may crash with a segmentation fault or bus error, but no clear indication where and why this happened. Such a crash can be caused by other things than array access out of bounds.
- Your program may continue running, but giving wrong results, since reading from outside the array probably gives you meaningless values.

For now, it is best to use the \texttt{at} method throughout.

\textbf{Array index out of bounds}

Indexing out of bounds can go undetected for a while:

\begin{verbatim}
Code:
vector<float> v(10,2);
for (int i=5; i<6; i--)
    cout << "element " << i << " is " << v[i] << endl;
\end{verbatim}

\begin{verbatim}
Output
[array] segmentation:
element -2841 is 0
element -2842 is 0
element -2843 is 0
element -2844 is 1.41531e-43
element -2845 is 1.8519e+28
element -2846 is 7.31695e+28
element -2847 is 2.56297e+08
element -2848 is 2.65628e+20
/bin/sh: line 1: 178 Segmentation fault: 11 ./segmentation
\end{verbatim}

\textbf{Review 11.3.} The following codes are not correct in some sense. How will this manifest itself?

\begin{verbatim}
Review
vector<int> a(5);
a[6] = 1.;
\end{verbatim}

\begin{verbatim}
vector<int> a(5);
a.at(6) = 1.;
\end{verbatim}

In some applications you will create an array, and gradually fill it, for instance in a loop. However, sometimes your elements are known in advance and you can write them out. Specifying these values while creating the array is called \textit{array initialization}, and there is more than one way to do so.

First of all, you can set a vector to a constant:

\subsection*{11.2 Going over all array elements}

If you need to consider all the elements in a vector, you typically use a \texttt{for} loop. There are various ways of doing this.

\textbf{A philosophical point}

Conceptually, a vector can correspond to a set of things, and the fact that they are indexed is purely incidental, or it can correspond to an ordered set, and the index is essential. If your algorithm requires you to access all elements, it is important to think about which of these cases apply, since there are two different mechanism.
11.2. Going over all array elements

11.2.1 Ranging over a vector

First of all consider the cases where you consider the vector as a collection of elements, and the loop functions like a mathematical ‘for all’.

**Range over elements**

You can write a range-based for loop, which considers the elements as a collection.

```cpp
for (float e : array)  // statement about element e
for (auto e : array)  // same, with type deduced by compiler
```

**Code:**

```cpp
code
#include <vector>

int main() {
    std::vector<int> numbers = {1,4,2,6,5};
    int tmp_max = -2000000000;
    for (auto v : numbers) {
        if (v > tmp_max) {
            tmp_max = v;
        }
    }
    std::cout << "Max: " << tmp_max << " (should be 6)" << std::endl;
    return 0;
}
```

**Output**

[array] dynamicmax:
Max: 6 (should be 6)

(You can spell out the type of the vector element, but such type specifications can be complex. In that case, using type deduction through the `auto` keyword is quite convenient.)

**So-called initializer lists** can also be used as a list denotation:

**Range over vector denotation**

```cpp
for (auto i : {2,3,5,7,9})
    std::cout << i << " ";
```

**Output**

[array] rangedenote:
2,3,5,7,9,

11.2.2 Ranging over the indices

If you actually need the index of the element, you can use a traditional `for` loop with loop variable.

**Indexing the elements**

You can write an indexed for loop, which uses an index variable that ranges from the first to the last element.

```cpp
for (int i = /* from first to last index */ )
    // statement about index i
```

Example: find the maximum element in the array, and where it occurs.
11. Arrays

Code:
```cpp
int tmp_idx = 0;
int tmp_max = numbers.at(tmp_idx);
for (int i=0; i<numbers.size(); i++) {
    int v = numbers.at(i);
    if (v>tmp_max) {
        tmp_max = v; tmp_idx = i;
    }
}
cout << "Max: " << tmp_max << " at index: " << tmp_idx << endl;
```

Output

[array] vecidxmax:
Max: 6.6 at index: 3

Exercise 11.4. Indicate for each of the following vector operations whether you prefer to use an indexed loop or a range-based loop. Give a short motivation.
- Count how many elements of a vector are zero.
- Find the location of the last zero.

Exercise 11.5. Find the element with maximum absolute value in a vector. Use:
```cpp
vector<int> numbers = {1,-4,2,-6,5};
```

Hint:
```cpp
#include <cmath>
absx = abs(x);
```

Exercise 11.6. Find the location of the first negative element in a vector. Which mechanism do you use?

Exercise 11.7. Check whether a vector is sorted.

11.2.3 Ranging by reference

Range over elements by reference

Range-based loop indexing makes a copy of the vector element. If you want to alter the vector, use a reference:
```cpp
for ( auto &e : my_vector)
    e = ....
```
11.3 Vector are a class

Above, you created vectors and used functions `at` and `size` on them. They used the dot-notation of class methods, and in fact vector form a `vector` class. You can have a vector of ints, floats, doubles, etcetera; the angle bracket notation indicates what the specific type stored in the vector is. You could say that the vector class is parametrized with the type (see chapter 22 for the details). We could say that `vector<int>` is a new data type, pronounced ‘vector-of-int’, and you can make variables of that type.

Vector copy

Vectors can be copied just like other datatypes:

Code:
```cpp
vector<float> v(5, 0), vcopy;

v.at(2) = 3.5;
vcopy = v;
vcopy.at(2) *= 2;

for ( auto & e : myvector )
    e *= 2;

cout << myvector.at(2) << endl;
```

Output:

[array] vectorcopy:
3.5, 7

(Can also use `const auto & e` to prevent copying, but also prevent altering data.)

Exercise 11.8. If you do the prime numbers project, you can now do exercise 52.16.

In a while loop, if you need an index, you need to maintain that index explicitly. There are then certain common idioms.

Example of increment indexing

Code:
```cpp
vector<int> numbers{3, 5, 7, 8, 9, 11};
int index{0};
while ( numbers[index++]%2==1 ) {
    cout << "The first even number\n"
        << "appears at index "
        << index << endl;
}
```

Output:

[loop] plusplus:
The first even number appears at index 4

Exercise 11.9. Exercise: modify the preceding code so that after the while loop `index` is the number of leading odd elements.
11. Arrays

11.3.1 Vector methods

There are several methods to the vector class. Some of the simpler ones are:

- `at`: index an element
- `size`: give the size of the vector
- `front`: first element
- `back`: last element

There are also methods relating to dynamic storage management, which we will get to next.

Exercise 11.10. Create a vector \( x \) of float elements, and set them to random values. Now normalize the vector in \( L_2 \) norm and check the correctness of your calculation, that is,

1. Compute the \( L_2 \) norm of the vector:
   \[
   \|v\| \equiv \sqrt{\sum_i v_i^2}
   \]

2. Divide each element by that norm;

3. The norm of the scaled vector should now be 1. Check this.

4. Bonus: your program may be printing 1, but is it actually 1? Investigate.

What type of loop are you using?

Your first encounter with templates

`vector` is a ‘templated class’: `vector<X>` is a vector-of-\( X \).

Code behaves as if there is a class definition for each type:

```
class vector<int> {
  public:
    size(); at(); // stuff
}  

class vector<float> {
  public:
    size(); at(); // stuff
}
```

Actual mechanism uses templating: the type is a parameter to the class definition. More later.

11.3.2 Vectors are dynamic

A vector can be grown or shrunk after its creation. For instance, you can use the `push_back` method to add elements at the end.

Dynamic vector extension

Extend a vector’s size with `push_back`:
11.4. Vectors and functions

Vectors act like any other datatype, so they can be used with functions: you can pass a vector as argument, or have it as return type. We will explore that in this section.

11.4.1 Pass vector to function

The mechanisms of parameters passing (section 7.4) apply to vectors too.

```cpp
vector<int> iarray;
vector<float> data;

iarray.reserve(100);
while ( ... )
    iarray.push_back( ... );
```
11. Arrays

*C difference:* There is a big difference here between C++ vectors and C arrays!

**Vector as function argument**

You can pass a vector to a function:

```cpp
double slope(vector<double> v) {
    return v.at(1)/v.at(0);
}
```

Vectors, like any argument, are passed by value, so the vector is actually copied into the function.

*C difference:* In C the array is not copied: you pass the address by value. Not the contents.

**Vector pass by value example**

```cpp
void set0(vector<float> v, float x) {
    v.at(0) = x;
    /* ... */
    vector<float> v(1);
    v.at(0) = 3.5;
    set0(v, 4.6);
    cout << v.at(0) << endl;
}
```

Output
[array] vectorpassnot:
3.5

Exercise 11.11. Revisit exercise 11.10 and introduce a function for computing the \( L_2 \) norm.

**Vector pass by reference**

If you want to alter the vector, you have to pass by reference:

```cpp
void set0(vector<float> &v, float x) {
    v.at(0) = x;
    /* ... */
    vector<float> v(1);
    v.at(0) = 3.5;
    set0(v, 4.6);
    cout << v.at(0) << endl;
}
```

Output
[array] vectorpassref:
4.6

**Vector pass by const reference**

Unless you alter the vector:

```cpp
int f(const vector<int> &ivec) { ... }
```

Not copied, not alterable.
No need for pointers!

The general guideline for parameter passing was
11.4. Vectors and functions

- pass by value if the argument is not altered;
- pass by reference if the argument is altered.

For vectors this matter gets another dimension: passing by value means copying, which is potentially expensive for vectors. The way out here is to pass by const reference which both prevents copying and prevents accidental altering; see section 18.2.

11.4.2 Vector as function return

You can have a vector as return type of a function.

Example: this function creates a vector, with the first element set to the size:

```cpp
code:

```vector<int> make_vector(int n) {
  vector<int> x(n);
  x.at(0) = n;
  return x;
}

/* ... */

```output

[array] vectorreturn:
x1 size: 10
zero element check: 10
```

Exercise 11.12. Write a function of one int argument n, which returns vector of length n, and which contains the first n squares.

Exercise 11.13. Write functions random_vector and sort to make the following main program work:

```cpp
int length = 10;
vector<float> values = random_vector(length);
vector<float> sorted = sort(values);
```

This creates a vector of random values of a specified length, and then makes a sorted copy of it.

Instead of making a sorted copy, sort in-place (overwrite original data with sorted data):

```cpp
int length = 10;
vector<float> values = random_vector(length);
sort(values); // the vector is now sorted
```

Find arguments for/against that approach.

(Note: C++ has sorting functions built in.)
Arrays

(See section 7.8.1 for the random function.)

**Exercise 11.14.** Write code to take a vector of integers, and construct two vectors, one containing all the odd inputs, and one containing all the even inputs. So:

<table>
<thead>
<tr>
<th>input:</th>
<th>output:</th>
</tr>
</thead>
<tbody>
<tr>
<td>5,6,2,4,5</td>
<td>5,5</td>
</tr>
<tr>
<td></td>
<td>6,2,4</td>
</tr>
</tbody>
</table>

Can you write a function that accepts a vector and produces two vectors as described?

### 11.5 Vectors in classes

You may want a class of objects that contain a vector. For instance, you may want to name your vectors.

```cpp
class named_field {
    private:
    vector<double> values;
    string name;
}
```

The problem here is when and how that vector is going to be created.

- If the size of the vector is statically determined, you can of course declare it with that size:

```cpp
class named_field {
    private:
    vector<double> values(25);
    string name;
}
```

- ... but in the more interesting case the size is determined during the runtime of the program. In that case you would to declare:

```cpp
typed_field velocity_field(25,"velocity");
```

specifying the size in the constructor of the object.

So now the question is, how do you allocate that vector in the object constructor?

One solution would be to specify a vector without size in the class definition, create a vector in the constructor, and assign that to the vector member of the object:

```cpp
typed_field( int n ) {
    values = vector<int>(n);
}
```

However, this has the effect that

- The constructor first creates `values` as a zero size vector,
- then it creates an anonymous vector of size `n`,
- and by assigning it, destroys the earlier created zero size vector.

This is somewhat inefficient, and the optimal solution is to create the vector as part of the **member initializer list**:
Create the contained vector

Use initializers for creating the contained vector:

```cpp
class named_field {
  private:
    vector<int> values;
  public:
    named_field( int n )
      : values(vector<int>(n)) {
    }
};
```

Less desirable method is creating in the constructor:

```cpp
named_field( int n ) {
  values = vector<int>(n);
};
```

### 11.5.1 Timing

Different ways of accessing a vector can have drastically different timing cost.

**Filling in vector elements**

You can push elements into a vector:

```cpp
vector<int> flex;
/* ... */
for (int i=0; i<LENGTH; i++)
  flex.push_back(i);
```

If you allocate the vector statically, you can assign with `at`:

```cpp
vector<int> stat(LENGTH);
/* ... */
for (int i=0; i<LENGTH; i++)
  stat.at(i) = i;
```

**Filling in vector elements**

With subscript:

```cpp
vector<int> stat(LENGTH);
/* ... */
for (int i=0; i<LENGTH; i++)
  stat[i] = i;
```

You can also use `new` to allocate*:

```cpp
int *stat = new int[LENGTH];
/* ... */
for (int i=0; i<LENGTH; i++)
  stat[i] = i;
```

*Considered bad practice. Do not use.

For `new`, see section 17.6.2. However, note that this mode of allocation is basically never needed.
11. Arrays

Timings are partly predictable, partly surprising:

**Timing the ways of filling a vector**

<table>
<thead>
<tr>
<th>Flexible time</th>
<th>Static at time</th>
<th>Static assign time</th>
<th>Static assign time to new</th>
</tr>
</thead>
<tbody>
<tr>
<td>2.445</td>
<td>1.177</td>
<td>0.334</td>
<td>0.467</td>
</tr>
</tbody>
</table>

The increased time for `new` is a mystery.

So do you use `at` for safety or `[]` for speed? Well, you could use `at` during development of the code, and insert

```cpp
#define at(x) operator[](x)
```

for production.

11.6 Wrapping a vector in an object

You may want to create objects that contain a vector, for instance because you want to add some methods.

```cpp
class namedvector {
  private:
    string name;
    vector<int> values;
  public:
    namedvector(int n, string name="unnamed")
      : name(name), values(vector<int>(n)) {};
    string rendered() {
      string render(name);
      render += ":";
      for (auto v : values)
        render += " "+atoi(v)+",";
      return render;
    }
  /* ... */
};
```

Unfortunately this means you may have to recreate some methods:

```cpp
int &at(int i) {
  return values.at(i);
}
```

11.7 Multi-dimensional cases

Unlike Fortran, C++ has little support for multi-dimensional arrays. If your multi-dimensional arrays are to model linear algebra objects, it would be good to check out the *Eigen* library. Here are some general remarks on multi-dimensional storage.
11.7. Multi-dimensional cases

11.7.1 Matrix as vector of vectors

Multi-dimensional vectors

Multi-dimensional is harder with vectors:

```cpp
vector<float> row(20);
vector<vector<float>> rows(10, row);
// alternative:
vector<vector<float>> rows(10);
for (auto &row : rows)
    row = vector<float>(20);
```

Create a row vector, then store 10 copies of that:

```cpp```
vector of vectors.

This is not the best implementation of a matrix, for instance because the elements are not contiguous. However, let’s continue with it for a moment.

Matrix class

```cpp
class matrix {
    private:
        vector<vector<double>> elements;
    public:
        matrix(int m, int n) {
            elements = vector<vector<double>>(m, vector<double>(n));
        }
        void set(int i, int j, double v) {
            elements.at(i).at(j) = v;
        }
        double get(int i, int j) {
            return elements.at(i).at(j);
        }
};
```

Exercise 11.15. Write `rows()` and `cols()` methods for this class that return the number of rows and columns respectively.

Exercise 11.16. Add methods such as `transpose`, `scale` to your matrix class. Implement matrix-matrix multiplication.

11.7.2 A better matrix class

You can make a ‘pretend’ matrix by storing a long enough `vector` in an object:

```cpp
class matrix {
    private:
        std::vector<double> the_matrix;
        int m, n;
    public:
```
11. Arrays

```c++
matrix(int m, int n) :
    m(m), n(n), the_matrix(m*n) {};
void set(int i, int j, double v) {
    the_matrix.at( i*n + j ) = v;
}
double get(int i, int j) {
    return the_matrix.at( i*n + j );
}
/* ... */
```

Exercise 11.17. In the matrix class of the previous slide, why are \(m, n\) stored explicitly, and not in the previous case?

The most important advantage of this is that it is compatible with the storage traditionally used in many libraries and codes.

The syntax for `set` and `get` can be improved.

Exercise 11.18. Write a method `element` of type `double&`, so that you can write

```c++
A.element(2,3) = 7.24;
```

11.8 Advanced topics

11.8.1 Iterators

You have seen how you can iterate over a vector

- by an indexed loop over the indices, and
- with a range-based loop over the indices.

There is a third way, which is actually the basic mechanism underlying the range-based looping.

An iterator is, in a metaphorical sense (see section 24.2.2 for details) a pointer to a vector element. Mirroring the index-loop convention of

```c++
for (int i=0; i<hi; i++)
    element = vec.at(i);
```

you can iterate:

```c++
for (auto elt_ptr=vec.begin(); elt_ptr!=vec.end(); ++elt_ptr)
    element = *elt_ptr;
```

Some remarks:

- This is one of the very few places where you need the asterisk in C++ for dereferencing; section 17.2. (However, the thing you are dereferencing is an iterator, not a pointer.)
- As with a normal loop, the `end` iterator point just beyond the end of the vector.
• You can do \textit{pointer arithmetic} on iterators, as you can see in the \texttt{++elt\_ptr} update part of the loop header.

Another illustration of pointer arithmetic on iterators is getting the last element of a vector:

\begin{verbatim}
Code:
vector<int> mydata(5,2);
mydata.push_back(35);
cout << mydata.size() << endl;
cout << mydata[mydata.size()-1] << endl;

Output [array] vectorend:
6
35
\end{verbatim}

\begin{verbatim}
Code:
vector<int> mydata(5,2);
mydata.push_back(35);
cout << mydata.size() << endl;
cout << *(--mydata.end()) << endl;

Output [array] vectorenditerator:
6
35
\end{verbatim}

\section*{11.8.2 Old-style arrays}

Static arrays are really an abuse of the equivalence of arrays and addresses of the C programming language. This appears for instance in parameter passing mechanisms.

For small arrays you can use a different syntax.

\begin{verbatim}
Code:
int numbers[] = {5,4,3,2,1};
cout << numbers[3] << endl;

Output [array] staticinit:
2
21
\end{verbatim}

This has the (minimal) advantage of not having the overhead of a class mechanism. On the other hand, it has a number of disadvantages:

• You can not query the size of an array by its name: you have to store that information separately in a variable.

• Passing such an array to a function is really passing the address of its first element, so it is always (sort of) by reference.

Range-based indexing works the same as with vectors:
11. Arrays

Code:

```cpp
int numbers[] = {1, 4, 2, 6, 5};
int tmp_max = numbers[0];
for (auto v : numbers)
    if (v > tmp_max)
        tmp_max = v;
cout << "Max: " << tmp_max << " (should be 6)" << endl;
```

Output: rangemax:

```
Max: 6 (should be 6)
```

Review 11.19. The following codes are not correct in some sense. How will this manifest itself?

```cpp
int a[5];
a[6] = 1.;
```

```
int a[5];
a.at(6) = 1.;
```

11.8.2.1 C-style arrays and subprograms

Arrays can be passed to a subprogram, but the bound is unknown there.

```cpp
void set_array( double *x, int size ) {
    for (int i=0; i<size; i++)
        x[i] = 1.41;
    /* ... */
    double array[5] = {11, 22, 33, 44, 55};
    set_array(array, 5);
}
```

Exercise 11.20. Rewrite the above exercises where the sorting tester or the maximum finder is in a subprogram.

Unlike with scalar arguments, array arguments can be altered by a subprogram: it is as if the array is always passed by reference. This is not strictly true: what happens is that the address of the first element of the array is passed. Thus we are really dealing with pass by value, but it is the array address that is passed rather than its value.

11.8.2.2 Multi-dimensional arrays

Multi-dimensional arrays can be declared and used with a simple extension of the prior syntax:

```cpp
float matrix[15][25];
for (int i=0; i<15; i++)
    for (int j=0; j<25; j++)
        // something with matrix[i][j]
```

Passing a multi-dimensional array to a function, only the first dimension can be left unspecified:
11.8. Advanced topics

```cpp
tvoid print12( int ar[][6] ) {
   cout << "Array[1][2]: " << ar[1][2] << endl;
   return;
}

int array[5][6];
array[1][2] = 3;
print12(array);
```

C/C++ row major

<table>
<thead>
<tr>
<th>(1,1)</th>
<th>(1,2)</th>
</tr>
</thead>
<tbody>
<tr>
<td>(2,1)</td>
<td></td>
</tr>
<tr>
<td>(3,1)</td>
<td></td>
</tr>
</tbody>
</table>

Physical:

| (1,1) (1,2) | (2,1) | (3,1) |

11.8.2.3 Memory layout

Puzzling aspects of arrays, such as which dimensions need to be specified and which not in a function call, can be understood by considering how arrays are stored in memory. The question then is how a two-dimensional (or higher dimensional) array is mapped to memory, which is linear.

- A one-dimensional array is stored in contiguous memory.
- A two-dimensional array is also stored contiguously, with first the first row, then the second, et cetera.
- Higher dimensional arrays continue this notion, with contiguous blocks of the highest so many dimensions.

As a result of this, indexing beyond the end of a row, brings you to the start of the next row:

```cpp
tvoid print06( int ar[][6] ) {
   cout << "Array[0][6]: " << ar[0][6] << endl;
   return;
}

int array[5][6];
array[1][0] = 35;
print06(array);
```

We can now also understand how arrays are passed to functions:

- The only information passed to a function is the address of the first element of the array;
- In order to be able to find location of the second row (and third, et cetera), the subprogram needs to know the length of each row.
- In the higher dimensional case, the subprogram needs to know the size of all dimensions except for the first one.

Victor Eijkhout
11.8.3 Stack and heap allocation

Entities stored in memory (variables, structures, objects) can exist in two locations: the stack and the heap.

- Every time a program enters a new scope, entities declared there are placed on top of the stack, and they are removed by the end of the scope.
- The heap is for entities that transcend scope, for instance because they are pointed-to by a pointer. The space of such objects can be returned to the free store at any time, so the heap can suffer from fragmentation.

The concepts of stack and heap do not appear in the C++ standard. However, the following description generally applies:

- Objects that obey scope are allocated on the stack, so that their memory is automatically freed control leaves the scope.
- Dynamically created objects, such as the target of a pointer, live on the heap because their lifetime is not subject to scope.

The existence of the second category is a source of memory leaks in languages such as C. This danger is greatly lessened in C++.

While in C the only way to create dynamic objects is by a call to malloc, in C++ a vector obeys scope, and therefore lives on the stack. If you wonder if this may lead to stack overflow, rest assured: only the descriptor, the part of the vector that remembers the size, is on the stack, while the actual data is on the heap. However, it is no longer subject to memory leaking, since the heap storage is deallocated when the vector object goes out of scope.

If you want heap memory that transcends scope you can use the smart pointer mechanism, which also guarantees against memory leaks. See chapter 16.

11.8.4 The Array class

In cases where an array will never change size it would be convenient to have a variant of the vector class that does not have the dynamic memory management facility. The array class seems to fulfill this role at first sight. However, it is limited to arrays where the size is known at compile time.

11.8.5 Span

The old C style arrays allowed for some operations that are harder to do with vectors. For instance, you could create a subset of an array with:

```c
double *x = (double*)malloc(N*sizeof(double));
double *subx = x+1;
```

In C++ you can write

```c
vector<double> x(N);
vector<double> subx(x.begin()+1,x.end());
```

but that allocates new storage.
If you really want two vector-like objects to share data there is the `span` class, which is in the STL of C++20. Until this standard is available you can use the Guideline Support Library (GSL), for instance implemented in https://github.com/Microsoft/GSL.

A span is little more than a pointer and a size, so it allows for the above use case. Also, it does not have the overhead of creating a whole new vector.

```cpp
Span

```vector`<double>` v;

```auto v_span = gsl::span<double>(v.data(), v.size());```

The `span` object has the same `at`, `data`, and `size` methods, and you can iterate over it, but it has no dynamic methods.

### 11.9 Exercises

**Exercise 11.21.** Given a vector of integers, write two loops;

1. One that sums all even elements, and
2. one that sums all elements with even indices.

Use the right type of loop.

**Exercise 11.22.** Program *bubble sort*: go through the array comparing successive pairs of elements, and swapping them if the second is smaller than the first. After you have gone through the array, the largest element is in the last location. Go through the array again, swapping elements, which puts the second largest element in the one-before-last location. Et cetera.

**Pascal’s triangle**

Pascal’s triangle contains binomial coefficients:

<table>
<thead>
<tr>
<th>Row</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>1</td>
<td>1</td>
</tr>
<tr>
<td>3</td>
<td>1</td>
<td>2</td>
</tr>
<tr>
<td>4</td>
<td>1</td>
<td>3</td>
</tr>
<tr>
<td>5</td>
<td>1</td>
<td>4</td>
</tr>
<tr>
<td>6</td>
<td>1</td>
<td>5</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>6</td>
</tr>
<tr>
<td>8</td>
<td>1</td>
<td>7</td>
</tr>
<tr>
<td>9</td>
<td>1</td>
<td>8</td>
</tr>
<tr>
<td>10</td>
<td>1</td>
<td>9</td>
</tr>
</tbody>
</table>

where

\[ \binom{r}{c} = \frac{r!}{c!(r-c)!} \]
The coefficients can be computed from the recurrence

\[
p_{rc} = \begin{cases} 
1 & c \equiv 1 \lor c \equiv r \\
p_{r-1,c-1} + p_{r-1,c} & \text{otherwise}
\end{cases}
\]

(There are other formulas. Why are they less preferable?)

**Exercise 11.23.**
- Write a class `pascal` so that `pascal(n)` is the object containing `n` rows of the above coefficients.
- Write a method `get(i, j)` that returns the `(i, j)` coefficient.
- Write a method `print` that prints the above display.
- First print out the whole pascal triangle; then:
- Write a method `print(int m)` that prints a star if the coefficient modulo `m` is nonzero, and a space otherwise.

```
* 
* * 
*   *
* * * *
*     *
*   * *
* * * * *
*     *
* * * * *
```

- The object needs to have an array internally. The easiest solution is to make an array of size `n x n`.
- Your program should accept:
  1. an integer for the size
  2. any number of integers for the modulo; if this is zero, stop, otherwise print stars as described above.

**Exercise 11.24.** Extend the Pascal exercise:
Optimize your code to use precisely enough space for the coefficients.

**Exercise 11.25.** A knight on the chess board moves by going two steps horizontally or vertically, and one step either way in the orthogonal direction. Given a starting position, find a sequence of moves that brings a knight back to its starting position. Are there starting positions for which such a cycle doesn’t exist?

**Exercise 11.26.** Put eight queens on a chessboard so that none threatens any other.

**Exercise 11.27.** From the ‘Keeping it REAL’ book, exercise 3.6 about Markov chains.
Chapter 12

Strings

12.1 Characters

Characters and ints

- Type char;
- represents '7-bit ASCII': printable and (some) unprintable characters.
- Single quotes: char c = 'a'

Char / int equivalence

Equivalent to (short) integer:

```
char ex = 'x';
int x_num = ex, y_num = ex+1;
char why = y_num;

cout << "x is at position " << x_num
    << endl;
cout << "one further lies " << why
    << endl;
```

Output

```
string intchar:
x is at position 120
one further lies y
```

Also: ’x’-’a’ is distance a--x

Remark 10 The translation from ’x’ to ascii code, and in particular the letters having consecutive values, are not guaranteed by the standard.

Exercise 12.1. Write a program that accepts an integer 1 · · · 26 and prints the so-manieth letter of the alphabet.

Extend your program so that if the input is negative, it prints the minus-so-manieth uppercase letter of the alphabet.

12.2 Basic string stuff
12. Strings

String declaration

```cpp
#include <string>
using std::string;

// .. and now you can use 'string'
```

(Do not use the C legacy mechanisms.)

String creation

A `string` variable contains a string of characters.

```cpp
string txt;
```

You can initialize the string variable or assign it dynamically:

```cpp
string txt("this is text");
string moretxt("this is also text");
txt = "and now it is another text";
```

Normally, quotes indicate the start and end of a string. So what if you want a string with quotes in it?

Quotes in strings

You can escape a quote, or indicate that the whole string is to be taken literally:

```cpp
string one("a b c"),
two("a \"b\" c"),
three( R"a "b "c"");
cout << one << endl;
cout << two << endl;
cout << three << endl;
```

That last mechanism is referred to as a raw string literal.

Concatenation

Strings can be concatenated:

```cpp
string my_string, space(" ");
my_string = "foo";
my_string += space + "bar";
cout << my_string << ": ": " << my_string.size() << endl;
```

String indexing

You can query the size:

```cpp
string five_text("fiver");
cout << five_text.size() << endl;
```

Introduction to Scientific Programming
or use subscripts:

```
string digits("0123456789");
cout << "char three: "
  << digits[2] << endl;
cout << "char four : "
  << digits.at(3) << endl;
```

### Ranging over a string

Same as ranging over vectors.

#### Range-based for:

```
cout << "By character: ";
for (char c : abc)
cout << c << " ";
cout << endl;
```

#### Ranging by index:

```
string abc = "abc";
cout << "By character: ";
for (int ic=0; ic<abc.size(); ic++)
cout << abc[ic] << " ";
cout << endl;
```

### Range with reference

Range-based for makes a copy of the element

You can also get a reference:

```
for (char &c : abc )
c += 1;
cout << "Shifted: " << abc << endl;
```

### Iterating over a string

```
for (auto c : some_string)
  // do something with the character 'c'
```

### Review 12.2. True or false?

1. ’0’ is a valid value for a char variable
2. "0" is a valid value for a char variable
3. "0" is a valid value for a string variable
4. ’a’+’b’ is a valid value for a char variable
Exercise 12.3. The oldest method of writing secret messages is the Caesar cypher. You would take an integer \( s \) and rotate every character of the text over that many positions:

\[
\text{s \equiv 3: } "acdz" \Rightarrow "dfgc".
\]

Write a program that accepts an integer and a string, and display the original string rotated over that many positions.

Exercise 12.4. (this continues exercise 12.3)

If you find a message encrypted with the Caesar cipher, can you decrypt it? Take your inspiration from the Sherlock Holmes story ‘The Adventure of the Dancing Men’, where he uses the fact that ‘e’ is the most common letter.

Can you implement a more general letter permutation cipher, and break it with the ‘dancing men’ approach?

More vector methods

Other methods for the vector class apply: insert, empty, erase, push_back, et cetera.

Code:

```
string five_chars;
cout << five_chars.size() << endl;
for (int i=0; i<5; i++)
    five_chars.push_back(’ ’);
cout << five_chars.size() << endl;
```

Methods only for string: find and such.

http://en.cppreference.com/w/cpp/string/basic_string

Exercise 12.5. Write a function to print out the digits of a number: 156 should print one five six. You need to convert a digit to a string first; can you think of more than one way to do that?

Start by writing a program that reads a single digit and prints its name.

For the full program it is easiest to generate the digits last-to-first. Then figure out how to print them reversed.

Exercise 12.6. Write a function to convert an integer to a string: the input 215 should give two hundred fifteen, et cetera.

Exercise 12.7. Write a pattern matcher, where a period . matches any one character, and \( x^* \) matches any number of ‘\( x \)’ characters.
12.3  String streams

You can concatenate string with the + operator. The less-less operator also does a sort of concatenation. It is attractive because it does conversion from quantities to string. Sometimes you may want a combination of these facilities: conversion to string, with a string as result.

For this you can use a string stream:

```
#include <sstream>
stringstream s;
s << "text" << 1.5;
cout << s.str() << endl;
```

12.4  Advanced topics

12.4.1 Conversation to/from string

There are various mechanisms for converting between strings and numbers.

- The C legacy mechanisms `sprintf` and `itoa`.
- `to_string`
- Above you saw the `stringstream`, section 12.3.
- The Boost library has a `lexical cast`.

Additionally, in C++17 there is the `charconv` header with `to_chars` and `from_chars`. These are low level routines that do not throw exceptions, do not allocate, and are each other’s inverses. The low level nature is for instance apparent in the fact that they work on character buffers (not null-terminated). Thus, they can be used to build more sophisticated tools on top of.

12.4.2 Unicode

C++ strings are essentially vectors of characters. A character is a single byte. Unfortunately, in these interweb days there are more characters around than fit in one byte. In particular, there is the Unicode standard that covers millions of characters. The way they are rendered is by an extendible encoding, in particular UTF8. This means that sometimes a single ‘character’, or more correctly glyph, takes more than one byte.

Example:
12. Strings

12.5 C strings

In C a string is essentially an array of characters. C arrays don’t store their length, but strings do have functions that implicitly or explicitly rely on this knowledge, so they have a terminator character: ASCII NULL. C strings are called null-terminated for this reason.
Chapter 13

Input/output

Most programs take some form of input, and produce some form of output. In a beginning course such as this, the output is of more importance than the input, and what output there is only goes to the screen, so that’s what we start by focusing on. We will also look at output to file, and input.

13.1 Screen output

In examples so far, you have used cout with its default formatting. In this section we look at ways of customizing the cout output.

Remark 11 Even after the material below you may find cout not particularly elegant. In fact, if you’ve programmed in C before, you may prefer the printf mechanism. The C++20 standard will have a new and improved mechanism that is as powerful as printf, but considerably more elegant.

Formatted output

- `cout` uses default formatting
- Possible: pad a number, use limited precision, format as hex, etc
- Many of these output modifiers need include <iomanip>

Normally, output of numbers takes up precisely the space that it needs:

<table>
<thead>
<tr>
<th>Code:</th>
<th>Output [io] conformat:</th>
</tr>
</thead>
</table>
| for (int i=1; i<200000000; i*=10)  
  cout << "Number: " << i << endl;  
  cout << endl; | Number: 1  
  Number: 10  
  Number: 100  
  Number: 1000  
  Number: 10000  
  Number: 100000  
  Number: 1000000  
  Number: 10000000 |

165
### Reserve space

You can specify the number of positions, and the output is right aligned by default:

```cpp
#include <iomanip>
using std::setw;
/* ... */
for (int i=1; i<200000000; i*=10)
  cout << "Number: " << setw(6) << i << endl;
// 'setw' applies only once:
cout << "Width is 6:" << endl;
for (int j=1; j<20000000; j*=10)
  cout << "Number: " << setw(6) << j << endl;
```

### Padding character

Normally, padding is done with spaces, but you can specify other characters:

```cpp
#include <iomanip>
using std::setfill;
using std::setw;
/* ... */
for (int i=1; i<200000000; i*=10)
  cout << "Number: " << setfill('.') << setw(6) << i << endl;
```

### Left alignment

Instead of right alignment you can do left:

```cpp
#include <iomanip>
using std::setfill;
using std::setw;
/* ... */
for (int i=1; i<200000000; i*=10)
  cout << "Number: " << setfill('.') << setw(6) << i << endl;
```
13.1. Screen output

**Code:**

```cpp
#include <iomanip>
using std::left;
using std::setfill;
using std::setw;
/* ... */
for (int i=1; i<200000000; i*=10)
    cout << "Number: "
        << left << setfill('.')
        << setw(6) << i << endl;
```

**Output**

```
[io] format left:
Number: 1....
Number: 10....
Number: 100...
Number: 1000..
Number: 10000.
Number: 100000
Number: 1000000
Number: 10000000
```

**Number base**

Finally, you can print in different number bases than 10:

**Code:**

```cpp
#include <iomanip>
using std::setbase;
using std::setfill;
/* ... */
cout << setbase(16)
    << setfill(' ');
for (int i=0; i<16; i++) {
    for (int j=0; j<16; j++)
        cout << i*16+j << " ";
    cout << endl;
}
```

**Output**

```
[io] format 16:
0 1 2 3 4 5 6 7 8 9 a b c d e f
10 11 12 13 14 15 16 17 18 19 1a 1b 1c 1d 1e 1f
20 21 22 23 24 25 26 27 28 29 2a 2b 2c 2d 2e 2f
```

*Exercise 13.1.* Make the first line in the above output align better with the other lines:

```
00 01 02 03 04 05 06 07 08 09 0a 0b 0c 0d 0e 0f
10 11 12 13 14 15 16 17 18 19 1a 1b 1c 1d 1e 1f
20 21 22 23 24 25 26 27 28 29 2a 2b 2c 2d 2e 2f
etc
```

**Hexadecimal**

Hex output is useful for addresses (chapter 17.2):
13. Input/output

**Code:**

```cpp
int i;
cout << "address of i, decimal: " << (long)&i << endl;
cout << "address of i, hex : " << std::hex << &i << endl;
```

**Output**

[pointer] coutpoint:

make[2]: 'coutpoint' is up to date.

Back to decimal:

```cpp
cout << hex << i << dec << j;
```

There is no standard modifier for outputting as binary.

### 13.1.1 Floating point output

#### Floating point precision

Use `setprecision` to set the number of digits before and after decimal point:

**Code:**

```cpp
#include <iomanip>
using std::left;
using std::setfill;
using std::setw;
using std::setprecision;
/* ... */
x = 1.234567;
for (int i=0; i<10; i++) {
    cout << setprecision(4) << x << endl;
    x *= 10;
}
```

**Output**

<table>
<thead>
<tr>
<th>formatfloat:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.235</td>
</tr>
<tr>
<td>12.35</td>
</tr>
<tr>
<td>123.5</td>
</tr>
<tr>
<td>1235</td>
</tr>
<tr>
<td>1.235e+04</td>
</tr>
<tr>
<td>1.235e+05</td>
</tr>
<tr>
<td>1.235e+06</td>
</tr>
<tr>
<td>1.235e+07</td>
</tr>
<tr>
<td>1.235e+08</td>
</tr>
<tr>
<td>1.235e+09</td>
</tr>
</tbody>
</table>

This mode is a mix of fixed and floating point. See the `scientific` option below for consistent use of floating point format.

#### Fixed point precision

Fixed precision applies to fractional part:

**Code:**

```cpp
x = 1.234567;
cout << fixed;
for (int i=0; i<10; i++) {
    cout << setprecision(4) << x << endl;
    x *= 10;
}
```

**Output**

<table>
<thead>
<tr>
<th>fix:</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.2346</td>
</tr>
<tr>
<td>12.3457</td>
</tr>
<tr>
<td>123.4567</td>
</tr>
<tr>
<td>1234.5670</td>
</tr>
<tr>
<td>12345.6700</td>
</tr>
<tr>
<td>123456.7000</td>
</tr>
<tr>
<td>1234567.0000</td>
</tr>
<tr>
<td>12345670.0000</td>
</tr>
<tr>
<td>123456700.0000</td>
</tr>
<tr>
<td>1234567000.0000</td>
</tr>
</tbody>
</table>

(Notice the rounding)
13.1. Screen output

Aligned fixed point output

Combine width and precision:

Code:
```cpp
x = 1.234567;
cout << fixed;
for (int i=0; i<10; i++) {
    cout << setw(10) << setprecision(4) << x << endl;
    x *= 10;
}
```

Output

[io] align:

```
1.2346
12.3457
123.4567
1234.5670
12345.6700
123456.7000
1234567.0000
12345670.0000
123456700.0000
1234567000.0000
```

Exercise 13.2. Use integer output to print real numbers aligned on the decimal:

Code:
```cpp
string quasifix(double);
int main() {
    for (auto x : { 1.5, 12.32, 123.456, 1234.5678 })
        cout << quasifix(x) << endl;
}
```

Output

[io] quasifix:

```
1.5
12.32
123.456
1234.5678
```

Use four spaces for both the integer and fractional part; test only with numbers that fit this format.

Scientific notation

Combining width and precision:

Code:
```cpp
x = 1.234567;
cout << scientific;
for (int i=0; i<10; i++) {
    cout << setw(10) << setprecision(4) << x << endl;
    x *= 10;
}
cout << endl;
```

Output

[io] iofsci:

```
13.1.2 Saving and restoring settings
```

```
ios::fmtflags old_settings = cout.flags();
cout.flags(old_settings);
int old_precision = cout.precision();
```

Victor Eijkhout
cout.precision(old_precision);

13.2 File output
Text output to file

The \texttt{iostream} is just one example of a \textit{stream}: general mechanism for converting entities to exportable form. In particular: file output works the same as screen output.

Use:

\begin{verbatim}
#include <fstream>
using std::ofstream;
/* ... */
ofstream file_out;
file_out.open("fio_example.out");
/* ... */
file_out << number << endl;
file_out.close();
\end{verbatim}

Compare: \texttt{cout} is a stream that has already been opened to your terminal ‘file’.

**Binary output**

Binary output: write your data byte-by-byte from memory to file. (Why is that better than a printable representation?)

\begin{verbatim}
ofstream file_out;
file_out.open("fio_binary.out",ios::binary);
/* ... */
file_out.write( (char*)(&number),4);
\end{verbatim}

13.3 Output your own classes

You have used statements like:

\begin{verbatim}
cout << "My value is: " << myvalue << endl;
\end{verbatim}

How does this work? The ‘double less’ is an operator with a left operand that is a stream, and a right operand for which output is defined; the result of this operator is again a stream. Recursively, this means you can chain any number of applications of \texttt{<<} together.
Redefine less-less

If you want to output a class that you wrote yourself, you have to define how the \texttt{\textless\textgreater} operator deals with your class.

```cpp
class container {
    /* ... */
    int value() const {
        /* ... */
    }
    /* ... */
    ostream &operator<<(ostream &os, const container &i) {
        os << "Container: " << i.value();
        return os;
    }
    /* ... */
    container eye(5);
    cout << eye << endl;
}
```

13.4 Output buffering

In C, the way to get a newline in your output was to include the character \texttt{\textbackslash n} in the output. This still works in C++, and at first it seems there is no difference with using \texttt{endl}. However, \texttt{endl} does more than breaking the output line: it performs a \texttt{std::flush}.

Output is usually not immediately written to screen or disc or printer: it is saved up in buffers. This can be for efficiency, because output a single character may have a large overhead, or it may be because the device is busy doing something else, and you don’t want your program to hang waiting for the device to free up.

However, a problem with buffering is the output on the screen may lag behind the actual state of the program. In particular, if your program crashes before it prints a certain message, does it mean that it crashed before it got to that line, or does it mean that the message is hanging in a buffer.

This sort of output, that absolutely needs to be handled when the statement is called, is often called \textit{logging} output. The fact that \texttt{endl} does a flush would mean that it would be good for logging output. However, it also flushes when not strictly necessary. In fact there is a better solution: \texttt{std::cerr} works just like \texttt{cout}, except it doesn’t buffer the output.

In other words, use \texttt{cout} for regular output, \texttt{cerr} for logging output, and use \texttt{\textbackslash n} instead of \texttt{endl}.

13.5 Input

Better terminal input

It is better to use \texttt{getline}. This returns a string, rather than a value, so you need to convert it with the following bit of magic:

```cpp
#include <iostream>
using std::cin;
using std::cout;
using std::endl;
```
13. Input/output

```cpp
#include <sstream>
#include <stringstream>

using std::stringstream;
/* ... */
std::string saymany;
int howmany;

cout << "How many times? ";
getline(cin, saymany);
stringstream saidmany(saymany);
saidmany >> howmany;
```

You can not use cin and getline in the same program.

13.5.1 File input

File input streams

Input file stream, method `open`, then use `getline` to read one line at a time:

```cpp
#include <fstream>

using std::ifstream;
/* ... */
ifstream input_file;
input_file.open("fox.txt");
string oneline;
while (getline(input_file, oneline)) {
    cout << "Got line: " << oneline << " >> " << endl;
}
```

End of file test

There are several ways of testing for the end of a file

- For text files, the `getline` function returns `false` if no line can be read.
- The `eof` function can be used after you have done a read.
- `EOF` is a return code of some library functions; it is not true that a file ends with an `EOT` character. Likewise you can not assume a `Control-D` or `Control-Z` at the end of the file.

Exercise 13.3. Put the following text in a file:

```
the quick brown fox
jummps over the
lazy dog.
```

Open the file, read it in, and count how often each letter in the alphabet occurs in it

Advanced note: You may that that `getline` always returns a `bool`, but that’s not true. If actually returns an `ifstream`. However, a conversion operator

```cpp
explicit operator bool() const;
```

exists for anything that inherits from `basic_ios`.  

Introduction to Scientific Programming
13.5.2 Input streams

Test, mostly for file streams: \texttt{is\_eof} \texttt{is\_open}
Chapter 14

Iterators, Algorithms, Ranges

14.1 Iterators

14.2 Algorithms

Many simple algorithms on arrays, testing ‘there is’ or ‘for all’, no longer have to be coded out in C++. They can now be done with a single function from `std::algorithm`.

- Test if any element satisfies a condition: `any_of`.
- Test if all elements satisfy a condition: `all_of`.
- Test if no elements satisfy a condition: `none_of`.
- Apply an operation to all elements: `for_each`.

The object to which the function applies is not specified directly; rather, you have to specify a start and end iterator.

**Use lambda to find any of**

Here is an example using `any_of` to find whether there is any even element in a vector:

```
vector<int> integers{1,2,3,5,7,10};
auto any_even = any_of
    (integers.begin(),integers.end(),
     [=] (int i) -> bool { return i%2==0; });
if (any_even) cout << "there was an even" << endl;
else cout << "none were even" << endl;
```

An example of `for_each`:

## Code:

```cpp
#include <algorithm>
using std::for_each;
/* ... */
vector<int> ints{3,4,5,6,7};
for_each
 ( ints.begin(), ints.end(),
   [] (int x) -> void {
     if (x%2==0)
       cout << x << endl;
   } );
```

Output

```
[stl] printeach:
4
6
```

See section 24.2.2 for iterators, in particular section 24.2.2.3 for algorithms with iterators, and section 7.6 for the use of lambda expressions.

### 14.3 Ranges

The C++20 standard contains a `ranges` header, which generalizes iterable objects into as-it-were streams, that can be connected with pipes.

We need to introduced two new concepts.

A range is an iterable object. The containers of the pre-17 STL are ranges, but some new ones have been added.

First of all, ranges provide a clearer syntax:

```cpp
vector data{2,3,1};
sort( begin(data),end(data) ); // open to accidents
ranges::sort(data);
```

A view is somewhat similar to a range, in the sense that you can iterate over it. The difference is that, unlike for instance a `vector`, a view is not a completely formed object. A view doesn’t own any data, and any elements you view in it get formed as you iterate over it. This is sometimes called lazy evaluation or lazy execution. Stated differently, its elements are constructed as they are being requested by the iteration over the view.

Views are composable: you can take one view, and pipe it into another one. If you need the resulting object, rather than the elements as a stream, you can call `to_vector`.

First two simple examples of views:

1. one formed by `transform`, which applies a function to each element of the range or view in sequence;
2. one formed by `filter`, which only yields those elements that satisfy some boolean test.

(We use an auxiliary function to turn a vector into a string.)

---

*Introduction to Scientific Programming*
14.3. Ranges

**Code:**

```cpp
vector<int> v{ 1,2,3,4,5,6 };
cout << "Original vector: " << endl;
auto times_two = v | transform([](int i) { return 2*i; });
cout << "Times two: " << vector_as_string(times_two | ranges::to_vector) << endl;
auto over_five = times_two | filter([](int i) { return i>5; });
cout << "Over five: " << vector_as_string(over_five | ranges::to_vector) << endl;
```

Output

```
[range] ft1:
```

Next to illustrate the composition of streams:

**Code:**

```cpp
vector<int> v{ 1,2,3,4,5,6 };
cout << "Original vector: " << endl;
auto times_two_over_five = v | transform([](int i) { return 2*i; }) | filter([](int i) { return i>5; });
cout << "Times two over five: " << vector_as_string(times_two_over_five | ranges::to_vector) << endl;
```

Output

```
[range] ft2:
```

Exercise 14.1. Make a vector that contains both positive and negative numbers. Use ranges to compute the minimum square root of the positive numbers.

Other available operations:
- dropping initial elements: `std::views::drop`
- reversing a vector: `std::views::drop`

Types of ranges:
- `std::ranges::input_range`: iterate forward at least once, as if you’re accepting input with `cin` and such.
- `std::ranges::forward_range`: can be iterated forward, (for instance with plus-plus), multiple times, as in a single-linked list.
- `std::ranges::bidirectional_range`: can be iterated in both directions, for instance with plus-plus and minus-minus.
- `std::ranges::random_access_range` items can be found in constant time, such as with square bracket indexing.

- `std::ranges::contiguous_range`: items are stored consecutively in memory, making address calculations possible.

Two concepts relate to storage, independent of the range concept:
- containers are ranges such as `vector` and `deque`, which own their data;
- views are ranges that do not own their data, for instance because they come from transforming a container or another view.

Adaptors take a range and return a view. They can do that by themselves, or chained:

```cpp
auto v = std::views::reverse(vec);
auto v = vec | std::views::reverse;
auto v = vec | std::views::reverse | /* more adaptors */ ;
```

14.3.1 Infinite sequences

Since views are lazily constructed, it is possible to have an infinite object – as long as you don’t ask for its last element.

```cpp
auto result = view::ints(10) // VLE ???
    | views::filter([] (const auto& value) { return value%2==0; } )
    | views::take(10) ;
```
Chapter 15

References

15.1 Reference

This section contains further facts about references, which you have already seen as a mechanism for parameter passing; section 7.4.2. Make sure you study that material first.

Passing a variable to a routine passes the value; in the routine, the variable is local.

```c++
void change_scalar(int i) {
    i += 1;
} /* ... */
number = 3;
cout << "Number is 3: " << number << endl;
change_scalar(number);
cout << "is it still 3? Let’s see: " << number << endl;
```

If you do want to make the change visible in the calling environment, use a reference:

```c++
void change_scalar_by_reference(int &i) { i += 1; }
```

There is no change to the calling program. (Some people who are used to C find this bad, since you can not see from the use of a function whether it passes by reference or by value.)

15.2 Pass by reference

If you use a mathematical style of subprograms, where some values go in, and a new entity comes out, in effect all the inputs can be copied. This style is called functional programming, and there is much to be said for it. For instance, it makes it possible for the compiler to reason about your program. The only thing you have to worry about is the cost of copying, if the inputs are of non-trivial size, such as arrays.

However, sometimes you want to alter the inputs, so instead of a copy you need a way of accessing the actual input object. That’s what references are invented for: to allow a subprogram access to the actual input entity.

A bonus of using references is that you do not incur the cost of copying. So what if you want this efficiency, but your program is really functional in design? Then you can use a const reference: the argument is passed by reference, but you indicate explicitly that the subprogram does not alter it, again allowing compiler optimizations.
15. References

Reference: change argument
A reference makes the function parameter a synonym of the argument.

```cpp
class BigDude {
    public:
        vector<double> array(5000000);
    }

    void f(BigDude d) {
        cout << d.array[0];
    }

    int main() {
        BigDude big;
        f(big); // whole thing is copied
    }
}
```

Instead write:

```cpp
void f(BigDude &thing) { .... };
Prevent changes:

```cpp
void f(const BigDude &thing) { .... };
```

Reference: save on copying

15.3 Reference to class members
Here is the naive way of returning a class member:

```cpp
class Object {
    private:
        SomeType thing;
    public:
        SomeType get_thing() {
            return thing;
        }
};
```

The problem here is that the return statement makes a copy of `thing`, which can be expensive. Instead, it is better to return the member by reference:

```cpp
SomeType &get_thing() {
    return thing;
};
```

The problem with this solution is that the calling program can now alter the private member. To prevent that, use a `const reference`:

```cpp
SomeType &get_thing() const {
    return thing;
};
```
In the above example, the function giving a reference was used in the left-hand side of an assignment. If you would use it on the right-hand side, you would not get a reference. The result of an expression can not be a reference.

Let’s again make a class where we can get a reference to the internals:

```cpp
class myclass {
private:
    int stored[0];
public:
    myclass(int i) : stored(i) {};
    int &data() { return stored; }
};
```

Now we explore various ways of using that reference on the right-hand side:
You see that, despite the fact that the method `data` was defined as returning a reference, you still need to indicate whether the left-hand side is a reference.

See section 18.1 for the interaction between `const` and references.

### 15.4 Reference to array members

You can define various operator, such as `+-*` arithmetic operators, to act on classes, with your own provided implementation; see section 10.4.6. You can also define the parentheses and square brackets operators, so make your object look like a function or an array respectively.

These mechanisms can also be used to provide safe access to arrays and/or vectors that are private to the object.

Suppose you have an object that contains an `int` array. You can return an element by defining the subscript (square bracket) operator for the class:

```cpp
class vector10 {
private:
  int array[10];
public:
  // ... */
  int operator[](int i) {
    return array[i];
  }
  int operator[](int i) {
    return array[i];
  }
}
```
Note that `return array[i]` will return a copy of the array element, so it is not possible to write

```
myobject[5] = 6;
```

For this we need to return a reference to the array element:

```
int& operator[](int i) {
    return array[i];
};
```

Your reason for wanting to return a reference could be to prevent the *copy of the return result* that is induced by the `return` statement. In this case, you may not want to be able to alter the object contents, so you can return a *const reference*:

```
const int& operator[](int i) {
    return array[i];
};
```

```
/* ... */
cout << v[2] << endl;
v[2] = -2;
cout << v[2] << endl;
*/
```

15.5 rvalue references

See the chapter about obscure stuff; section 26.4.3.
Chapter 16

Pointers

Pointers are an indirect way of associating an entity with a variable name. Consider for instance self-referential data structures:

A list is a node that functions as the head, and which has a tail that is a list.

```cpp
class Node {
private:
    int value;
    Node tail;
    /* ... */
};
```

This does not work: would take infinite memory.

```cpp
class Node {
private:
    int value;
    PointToNode tail;
    /* ... */
};
```

PointToNode 'points' to the first node of the tail.

This chapter will explain C++ smart pointers, and give some uses for them.

16.1 The ‘arrow’ notation

Members from pointer

- If \( x \) is object with member \( y \):
  \( x.y \)
- If \( xx \) is pointer to object with member \( y \):
  \( xx->y \)
- In class methods \( this \) is a pointer to the object, so:

```cpp
class x {
    int y;
    x(int v) {
        this->y = v;
    }
}
```
16. Pointers

16.2 Making a shared pointer

Smart pointers are used the same way as old-style pointers in C. If you have an object $\text{Obj} \ X$ with a member $y$, you access that with $x.y$; if you have a pointer $x$ to such an object, you write $x->y$.

So what is the type of this latter $x$ and how did you create it?

Use of a shared pointer

Same as C-pointer syntax:

```
HasX xobj(5);
cout << xobj.value() << endl;
xobj.set(6);
cout << xobj.value() << endl;
auto xptr = make_shared<HasX>(5);
cout << xptr->value() << endl;
xptr->set(6);
cout << xptr->value() << endl;
```

Output

[pointer] pointx:
make[2]: 'pointx' is up to date.

Creating a shared pointer

Allocation and pointer in one:

```
shared_ptr<Obj> X = make_shared<Obj>( /* constructor args */ );
// or:
auto X = make_shared<Obj>( /* args */ );
```

Simple example

Simple class that stores one number:

```
class HasX {
    private:
    double x;
    public:
    HasX( double x ) : x(x) {};
    auto value() { return x; };
    void set(double xx) { x = xx; };
};
```

Headers for smart pointers

Using shared pointers requires at the top of your file:

```
#include <memory>
using std::shared_ptr;
```
16.2. Making a shared pointer

What's the point of pointers?

Pointers make it possible for two variables to own the same object.

```cpp
using std::make_shared;
```

**Code:**

```cpp
auto xptr = make_shared<HasX>(5);
auto yptr = xptr;
cout << xptr->get() << endl;
yptr->set(6);
cout << xptr->get() << endl;
```

**Output**

```
[pointer] twopoint:
make[2]: ‘twopoint’ is up to date.
```

Pointers to arrays

The constructor syntax is a little involved for vectors:

```cpp
auto x = make_shared<vector<double>>(vector<double>{1.1,2.2});
```

16.2.1 Pointers and arrays

Linked lists

The prototypical example use of pointers is in linked lists. Consider a class `Node` with

• a data value to store, and

• a pointer to another `Node`, or `nullptr` if none.

Constructor sets the data value:

```cpp
class Node {
private:
    int datavalue{0};
    shared_ptr<Node> tail_ptr{nullptr};
public:
    Node() {}  
    Node(int value) : datavalue(value) {};
    int value() { return datavalue; };
```

Set next / test if there is a next:

```cpp
bool has_next() {
    return tail_ptr!=nullptr; }
```

List usage

Example use:

```cpp
auto first = make_shared<Node>(23), second = make_shared<Node>(45);
first->set_tail(second);
cout << "List length: " << first->list_length() << endl;
cout << first->print();
```

```
Victor Eijkhout
187
```
Linked lists and recursion

Many operations on linked lists can be done recursively:

```cpp
int Node::list_length() {
    if (!has_next()) return 1;
    else return 1 + tail_ptr->list_length();
}
```

Exercise 16.1. Write a method `set_tail` that sets the tail of a node.

```cpp
Node one;
one.set_tail(two); // what is the type of 'two'?
cout << one.list_length() << endl; // prints 2
```

Exercise 16.2. Write a recursive `append` method that appends a node to the end of a list:

```cpp
code:
auto first = make_shared<Node>(23),
    second = make_shared<Node>(45),
    third = make_shared<Node>(32);
first->append(second);
first->append(third);
first->print();
```

Exercise 16.3. Write a recursive `insert` method that inserts a node in a list, such that the list stays sorted:

```cpp
code:
auto first = make_shared<Node>(23),
    second = make_shared<Node>(45),
    third = make_shared<Node>(32);
first->insert(second);
first->insert(third);
first->print();
```

Assume that the new node always comes somewhere after the head node.

Exercise 16.4. For a more sophisticated approach to linked lists, do the exercises in section 65.1.2.
Exercises

16.5. If you are doing the prime numbers project (chapter 52) you can now do exercise 52.9.2.

16.2.2 Smart pointers versus address pointers

Pointers don’t go with addresses

The oldstyle `&y` address pointer can not be made smart:

```cpp
auto p = shared_ptr<HasY>( &y );
p->y = 3;
cout << "Pointer's y: "
   << p->y << endl;
```

gives:

```
address(56325,0x7fff977cc380) malloc: *** error for object
0x7ffeeb9caf08: pointer being freed was not allocated
```

Smart pointers are much better than old style pointers

```
Obj *X;
*X = Obj{ /* args */ };
```

There is a final way of creating a shared pointer where you cast an old-style `new` object to shared pointer

```
auto p = shared_ptr<Obj>( new Obj );
```

This is not the preferred mode of creation, but it can be useful in the case of weak pointers; section 16.5.4.

16.3 Garbage collection

The big problem with C-style pointers is the chance of a memory leak. If a pointer to a block of memory goes out of scope, the block is not returned to the Operating System (OS), but it is no longer accessible.

```cpp
// the variable 'array' doesn't exist
{
  // attach memory to 'array':
  double *array = new double[25];
  // do something with array
}
// the variable 'array' does not exist anymore
// but the memory is still reserved.
```

Shared and unique pointers do not have this problem: if they go out of scope, or are overwritten, the destructor on the object is called, thereby releasing any allocated memory.

An example.

Reference counting illustrated

We need a class with constructor and destructor tracing:

```cpp
class thing {
```
16. Pointers

```cpp
public:
  thing() { cout << ".. calling constructor\n"; }
  ~thing() { cout << ".. calling destructor\n"; }
};
```

### Pointer overwrite

Let’s create a pointer and overwrite it:

**Code:**

```cpp
cout << "set pointer1" << endl;
auto thing_ptr1 = make_shared<thing>();
cout << "overwrite pointer" << endl;
thing_ptr1 = nullptr;
```

**Output**

```
[pointer] ptr1:
set pointer1
.. calling constructor
overwrite pointer
.. calling destructor
```

However, if a pointer is copied, there are two pointers to the same block of memory, and only when both disappear, or point elsewhere, is the object deallocated.

### Pointer copy

**Code:**

```cpp
cout << "set pointer2" << endl;
auto thing_ptr2 = make_shared<thing>();
cout << "set pointer3 by copy" << endl;
auto thing_ptr3 = thing_ptr2;
cout << "overwrite pointer2" << endl;
thing_ptr2 = nullptr;
cout << "overwrite pointer3" << endl;
thing_ptr3 = nullptr;
```

**Output**

```
[pointer] ptr2:
set pointer2
.. calling constructor
set pointer3 by copy
 overwrite pointer2
 overwrite pointer3
.. calling destructor
```

### 16.4 More about pointers

#### 16.4.1 Get the pointed data

Most of the time, accessing the target of the pointer through the arrow notation is enough. However, if you actually want the object, you can get it with `get`. Note that this does not give you the pointed object, but a traditional pointer.

**Getting the underlying pointer**

```cpp
X->y;
// is the same as
X.get()->y;
// is the same as
(*X.get()).y;
```
16.5 Advanced topics

16.5.1 Unique pointers

Shared pointers are fairly easy to program, and they come with lots of advantages, such as the automatic memory management. However, they have more overhead than strictly necessary because they have a reference count mechanism to support the memory management. Therefore, there exists a unique pointer, unique_ptr, for cases where an object will only ever be ‘owned’ by one pointer. In that case, you can use a C-style bare pointer for non-owning references.

16.5.2 Base and derived pointers

Suppose you have base and derived classes:

```cpp
class A {}
class B : public A {}
```

Just like you could assign a B object to an A variable:

```cpp
B b_object;
A a_object = b_object;
```

is it possible to assign a B pointer to an A pointer?

The following construct makes this possible:

```cpp
auto a_ptr = shared_pointer<A>( make_shared<B>() );
```

Note: this is better than

```cpp
auto a_ptr = shared_pointer<A>( new B() );
```

Again a reason we don’t need new anymore!

16.5.3 Shared pointer to ‘this’

Inside an object method, the object is accessible as this. This is a pointer in the classical sense. So what if you want to refer to ‘this’ but you need a shared pointer?

For instance, suppose you’re writing a linked list code, and your node class has a method prepend_or_append that gives a shared pointer to the new head of the list.

Your code would start something like this, handling the case where the new node is appended to the current:

```cpp
auto y = make_shared<HasY>(5);
cout << y << endl;
y.get()->y = 6;
cout << ( *y.get() ).y << endl;
```
shared_pointer<node> node::append
    
    // if (other->value>this->value) {
    //     this->tail = other;
    return this->shared_from_this();

But now you need to return this node, as a shared pointer. But this is a node*, not a shared_ptr<node>.
The solution here is that you can return

return this->shared_from_this();

if you have defined your node class to inherit from what probably looks like magic:

class node : public enable_shared_from_this

Note that you can only return a shared_from_this if already a valid shared pointer to that object exists.

16.5.4 Weak pointers

In addition to shared and unique pointers, which own an object, there is also weak_ptr which creates a
weak pointer. This pointer type does not own, but at least it knows when it dangles.

weak_ptr<R> wp;
shared_ptr<R> sp( new R );
sp->call_member();
wp = sp;

// access through new shared pointer:
auto p = wp.lock();
if (p) {
    p->call_member();
}
if (!wp.expired()) { // not thread-safe!
    wp.lock()->call_member();
}

There is a subtlety with weak pointers and shared pointers. The call

auto sp = shared_ptr<Obj>( new Obj );

creates first the object, then the ‘control block’ that counts owners. On the other hand,

auto sp = make_shared<Obj>();

does a single allocation for object and control block. However, if you have a weak pointer to such a
single object, it is possible that the object is destructed, but not de-allocated. On the other hand, using

auto sp = shared_ptr<Obj>( new Obj );

creates the control block separately, so the pointed object can be destructed and de-allocated. Having a
weak pointer to it means that only the control block needs to stick around.
16.5.5 Null pointer

In C there was a macro `NULL` that, only by convention, was used to indicate null pointers: pointers that do not point to anything. C++ has the `nullptr`, which is an object of type `std::nullptr_t`.

There are some scenarios where this is useful, for instance, with polymorphic functions:

```cpp
void f(int);
void f(int*);
```

Calling `f(ptr)` where the point is `NULL`, the first function is called, whereas with `nullptr` the second is called.

Unfortunately, dereferencing a `nullptr` does not give an exception.

16.5.6 Opaque pointer

The need for opaque pointers `void*` is a lot less in C++ than it was in C. For instance, contexts can often be modeled with captures in closures (chapter 7.6). If you really need a pointer that does not `a priori` know what it points to, use `std::any`, which is usually smart enough to call destructors when needed.

```
std::any a = 1;
cout << a.type().name() << "\": " << std::any_cast<int>(a) << endl;

a = 3.14;
cout << a.type().name() << "\": " << std::any_cast<double>(a) << endl;

a = true;
cout << a.type().name() << "\": " << std::any_cast<bool>(a) << endl;

try {
    a = 1;
    cout << std::any_cast<float>(a) << endl;
} catch (const std::bad_any_cast& e) {
    cout << e.what() << endl;
}
```

Output [pointer] any:

```
make[2]: 'any' is up to date.
```

16.5.7 Pointers to non-objects

In the introduction to this chapter we argued that many of the uses for pointers that existed in C have gone away in C++, and the main one left is the case where multiple objects share ‘ownership’ of some other object.

You can still make shared pointers to scalar data, for instance to an array of scalars. You then get the advantage of the memory management, but you do not get the `size` function and such that you would have if you’d used a `vector` object.

Here is an example of a pointer to a solitary double:
16. Pointers

It is possible to initialize that double:

```c++
// shared pointer to initialized double
auto array = make_shared<double>(50);
double *ptr = array.get();
cout << ptr[0] << endl;
```

Output
[pointer] ptrdoubleinit:
50

16.6 Smart pointers vs C pointers

We remark that there is less need for pointers in C++ than there was in C.

- To pass an argument by reference, use a reference. Section 7.4.
- Strings are done through `std::string`, not character arrays; see 12.
- Arrays can largely be done through `std::vector`, rather than `malloc`; see 11.
- Traversing arrays and vectors can be done with ranges; section 11.2.
- Anything that obeys a scope should be created through a constructor, rather than using `malloc`.

Legitimate needs:

- Linked lists and Directed Acyclic Graphs (DAGs); see the example in section 65.1.2.
- Objects on the heap.
- Use `nullptr` as a signal.
Chapter 17

C-style pointers and arrays

17.1 What is a pointer

The term pointer is used to denote a reference to a quantity. The reason that people like to use C as high performance language is that pointers are actually memory addresses. So you’re programming ‘close to the bare metal’ and are in fargoing control over what your program does. C++ also has pointers, but there are fewer uses for them than for C pointers: vectors and references have made many of the uses of C-style pointers obsolete.

17.2 Pointers and addresses, C style

You have learned about variables, and maybe you have a mental concept of variables as ‘named memory locations’. That is not too far of: while you are in the (dynamic) scope of a variable, it corresponds to a fixed memory location.

Exercise 17.1. When does a variable not always correspond to the same location in memory?

There is a mechanism of finding the actual address of a variable: you prefix its name by an ampersand. This address is integer-valued, but its range is actually greater than of the int type.

**Memory addresses**

If you have an int i, then &i is the address of i.

An address is a (long) integer, denoting a memory address. Usually it is rendered in hexadecimal notation. C style:

```
int i;
printf("address of i: %ld\n", (long)&i);
printf(" same in hex: %lx\n", (long)&i);
```

Output

```
[pointer] printfpoint:
make[2]: ‘printfpoint’ is up to date.
```

and C++:
17. C-style pointers and arrays

**Code:**

```cpp
int i;
cout << "address of i, decimal: " << (long)&i << endl;
cout << "address of i, hex : " << std::hex << &i << endl;
```

**Output**

[pointer] coutpoint:

make[2]: 'coutpoint' is up to date.

Note that this use of the ampersand is different from defining references; compare section 7.4.2. However, there is never a confusion which is which since they are syntactically different.

You could just print out the address of a variable, which is sometimes useful for debugging. If you want to store the address, you need to create a variable of the appropriate type. This is done by taking a type and affixing a star to it.

**Address types**

The type of `&i` is `int*`, pronounced ‘int-star’, or more formally: ‘pointer-to-int’.

You can create variables of this type:

```cpp
int i;
int* addr = &i;
```

Now if you have have a pointer that refers to an int:

```cpp
int i;
int* iaddr = &i;
```

you can use (for instance print) that pointer, which gives you the address of the variable. If you want the value of the variable that the pointer points to, you need to dereference it.

**Dereferencing**

Using `*addr` ‘dereferences’ the pointer: gives the thing it points to; the value of what is in the memory location.

**Code:**

```cpp
int i;
int* addr = &i;
i = 5;
cout << *addr << endl;
i = 6;
cout << *addr << endl;
```

**Output**

[pointer] cintpointer:

make[2]: 'cintpointer' is up to date.

**Illustration**

---

*Introduction to Scientific Programming*
17.3 Arrays and pointers

Illustration

```
int x = 6;
"x"
6
946

int y = x;
"x" "y"
6 6
946 958
```

*addr is the address of i.
*You set i to 5; nothing changes about addr. This has the effect of writing 5 in the memory location of i.
*The first cout line dereferences addr, that is, looks up what is in that memory location.
*Next you change i to 6, that is, you write 6 in its memory location.
*The second cout looks in the same memory location as before, and now finds 6.

The syntax for declaring a pointer-to-sometype allows for a small variation, which indicates the two way you can interpret such a declaration.

**Star stuff**

Equivalent:

*int* addr: addr is an int-star, or
*int* addr: *addr is an int.

The notion int* addr is equivalent to int *addr, and semantically they are also the same: you could say that addr is an int-star, or you could say that *addr is an int.

17.3 Arrays and pointers

In section 11.8.2 you saw the treatment of static arrays in C++. Examples such as:
void set_array(double *x, int size) {
    for (int i=0; i<size; i++)
        x[i] = 1.41;
    
    double array[5] = {11,22,33,44,55};
    set_array(array,5);
    cout << array[0] << "...." << array[4] << endl;
}

show that, even though an parameters are normally passed by value, that is through copying, array parameters can be altered. The reason for this is that there is no actual array type, and what is passed is a pointer to the first element of the array. So arrays are still passed by value, just not the ‘value of the array’, but the value of its location.

So you could pass an array like this:

void array_set_star(double *ar, int idx, double val) {
    ar[idx] = val;
}

array_set_star(array,2,4.2);

Array and pointer equivalence

Array and memory locations are largely the same:

Code:

```cpp
double array[5] = {11,22,33,44,55};
double *addr_of_second = &array[1];
cout << *addr_of_second << endl;
array[1] = 7.77;
cout << *addr_of_second << endl;
```

Output [pointer] arrayaddr:
make[2]: ‘arrayaddr’ is up to date.

Array passing to function

When an array is passed to a function, it behaves as an address:

Code:

```cpp
void set_array(double *x, int size) {
    for (int i=0; i<size; i++)
        x[i] = 1.41;
    
    double array[5] = {11,22,33,44,55};
    set_array(array,5);
    cout << array[0] << "...." << array[4] << endl;
}
```

Output [pointer] arraypass:
make[2]: ‘arraypass’ is up to date.

Note that these arrays don’t know their size, so you need to pass it.

Dynamic allocation

You can dynamically reserve memory with new, which gives a something-star:

```cpp
double *x;
x = new double[27];
```
The `new` operator is only for C++: in C you would use `malloc` to dynamically allocate memory. The above example would become:

```c
double *x;
x = (double*) malloc( 27 * sizeof(double) );
```

Note that `new` takes the number of elements, and deduces the type (and therefore the number of bytes per element) from the context; `malloc` takes an argument that is the number of bytes. The `sizeof` operator then helps you in determining the number of bytes per element.

### 17.4 Pointer arithmetic

#### Pointer arithmetic

`pointer arithmetic` uses the size of the objects it points at:

```c
double *addr_of_element = array;
cout << *addr_of_element;
addr_of_element = addr_of_element+1;
cout << *addr_of_element;
```

Increment add size of the array element, 4 or 8 bytes, not one!

**Exercise 17.2.** Write a subroutine that sets the i-th element of an array, but using pointer arithmetic: the routine should not contain any square brackets.

### 17.5 Multi-dimensional arrays

#### Multi-dimensional arrays

After

```c
double x[10][20];
```

a row `x[3]` is a `double*`, so is `x` a `double**`?

Was it created as:

```c
double **x = new double*[10];
for (int i=0; i<10; i++)
    x[i] = new double[20];
```

No: multi-d arrays are contiguous.

### 17.6 Parameter passing

#### C++ pass by reference

C++ style functions that alter their arguments:

```c
void inc(int &i) { i += 1; }
```
C-style pointers and arrays

```c
int main() {
    int i=1;
    inc(i);
    cout << i << endl;
    return 0;
}
```

C-style pass by reference

In C you cannot pass-by-reference like this. Instead, you pass the address of the variable `i` by value:

```c
void inc(int *i) { *i += 1; }
int main() {
    int i=1;
    inc(&i);
    cout << i << endl;
    return 0;
}
```

Now the function gets an argument that is a memory address: `i` is an int-star. It then increases `*i`, which is an int variable, by one.

Note how again there are two different uses of the ampersand character. While the compiler has no trouble distinguishing them, it is a little confusing to the programmer.

Exercise 17.3. Write another version of the `swap` function:

```c
void swap(/* something with i and j */ { /* your code */ }
int main() {
    int i=1, j=2;
    swap(/* something with i and j */);
    cout << "check that i is 2: " << i << endl;
    cout << "check that j is 1: " << i << endl;
    return 0;
}
```

Hint: write C++ code, then insert stars where needed.

17.6.1 Allocation

In section 11.8.2 you learned how to create arrays that are local to a scope:

```c
if (something) {
    double ar[25];
} else {
    double ar[26];
}
ar[0] = // there is no array!
```
The array `ar` is created depending on if the condition is true, but after the conditional it disappears again. The mechanism of using `new` (section 17.6.2) allows you to allocate storage that transcends its scope:

**Declaration and allocation**

```cpp
double *array;
if (something) {
    array = new double[25];
} else {
    array = new double[26];
}
```

(Size in doubles, not in bytes as in C)

**Memory leak1**

```cpp
void func() {
    double *array = new double[large_number];
    // code that uses array
}
int main() {
    func();
}
```

• The function allocates memory
• After the function ends, there is no way to get at that memory
⇒ memory leak.

**Memory leaks**

```cpp
for (int i=0; i<large_num; i++) {
    double *array = new double[1000];
    // code that uses array
}
```

Every iteration reserves memory, which is never released: another memory leak.

Your code will run out of memory!

**De-allocation**

Memory allocated with `new` does not disappear when you leave a scope. Therefore you have to delete the memory explicitly:

```cpp
delete (array);
```

The C++ `vector` does not have this problem, because it obeys scope rules.

**Stop using C!**

No need for `malloc` or `new`
• Use `std::string` for character arrays, and
• `std::vector` for everything else.

No performance hit if you don’t dynamically alter the size.
17. C-style pointers and arrays

17.6.1.1 Malloc

The keywords `new` and `delete` are in the spirit of C style programming, but don’t exist in C. Instead, you use `malloc`, which creates a memory area with a size expressed in bytes. Use the function `sizeof` to translate from types to bytes:

```
Allocation in C
int n;
double *array;
array = malloc( n*sizeof(double) );
if (!array)
    // allocation failed!
```

17.6.1.2 Allocation in a function

The mechanism of creating memory, and assigning it to a ‘star’ variable can be used to allocate data in a function and return it from the function.

```
Allocation in a function

void make_array( double **a, int n ) {
    *a = new double[n];
}
int main() {
    double *array;
    make_array(&array,17);
}
```

Note that this requires a ‘double-star’ or ‘star-star’ argument:

- The variable `a` will contain an array, so it needs to be of type `double*`;
- but it needs to be passed by reference to the function, making the argument type `double**`;
- inside the function you then assign the new storage to the `double*` variable, which is `*a`.

Tricky, I know.

17.6.2 Use of new

`Before doing this section, make sure you study section 17.3.`

There is a dynamic allocation mechanism that is much inspired by memory management in C. Don’t use this as your first choice.

Use of `new` uses the equivalence of array and reference.

```
void make_array( int **new_array, int length ) {
    *new_array = new int[length];
}
/* ... */
int *the_array;
make_array(&the_array,10000);
```

Since this is not scoped, you have to free the memory yourself:
class with_array{
private:
  int *array;
  int array_length;
public:
  with_array(int size) {
    array_length = size;
    array = new int[size];
  }
  ~with_array() {
    delete array;
  }
};

/* ... */
with_array thing_with_array(12000);

Notice how you have to remember the array length yourself? This is all much easier by using a `std::vector`. See [http://www.cplusplus.com/articles/37Mf92yv/](http://www.cplusplus.com/articles/37Mf92yv/).

The `new` mechanism is a cleaner variant of `malloc`, which was the dynamic allocation mechanism in C. Malloc is still available, but should not be used. There are even very few legitimate uses for `new`.

### 17.7 Memory leaks

Pointers can lead to a problem called *memory leaking*: there is memory that you have reserved, but you have lost the ability to access it.

In this example:

```cpp
double *array = new double[100];
// ...
array = new double[105];
```

memory is allocated twice. The memory that was allocated first is never release, because in the intervening code another pointer to it may have been set. However, if that doesn’t happen, the memory is both allocated, and unreachable. That’s what memory leaks are about.

### 17.8 Const pointers

A pointer can be constant in two ways:

1. It points to a block of memory, and you can not change where it points.
2. What it points to is fixed, and the contents of that memory can also not be altered.

To illustrate the non-const behavior:
17. C-style pointers and arrays

Code:
```c
int value = 5;
int *ptr = &value;
*ptr += 1;
cout << "value: " << value << endl;
cout << "*ptr: " << *ptr << endl;
ptr += 1;
```

Output

[pointer] starconst1:
```
value: 6
*ptr: 6
random memory: 73896
```

A pointer that is constant in the first sense:
```c
int value = 5;
int *const ptr = &value;
/* DOES NOT COMPILE: cannot assign to variable 'ptr' with const-qualified type 'int *const'
ptr += 1;
*/
```

You can also make a pointer to a constant integer:
```c
const int value = 5; // value is const
/* DOES NOT COMPILE: cannot convert const int* to int*
int *ptr = &value;
*/
```
Chapter 18

Const

The keyword `const` can be used to indicate that various quantities can not be changed. This is mostly for programming safety: if you declare that a method will not change any members, and it does so (indirectly) anyway, the compiler will warn you about this.

### 18.1 Const arguments

The use of const arguments is one way of protecting you against yourself. If an argument is conceptually supposed to stay constant, the compiler will catch it if you mistakenly try to change it.

**Constant arguments**

Function arguments marked `const` can not be altered by the function code. The following segment gives a compilation error:

```cpp
void f(const int i) {
    i++; // Error: i is const
}
```

### 18.2 Const references

A more sophisticated use of `const` is the `const reference`:

```cpp
void f(const int &i) { .... }
```

This may look strange. After all, references, and the pass-by-reference mechanism, were introduced in section 7.4 to return changed values to the calling environment. The `const` keyword negates that possibility of changing the parameter.

But there is a second reason for using references. Parameters are passed by value, which means that they are copied, and that includes big objects such as `std::vector`. Using a reference to pass a vector is much less costly in both time and space, but then there is the possibility of changes to the vector propagating back to the calling environment.

Consider a class that has methods that return an internal member by reference, once as `const reference` and once not:
18. Const

We can make visible the difference between pass by value and pass by const-reference if we define a class where the *copy constructor* explicitly reports itself:

```cpp
class has_int {
private:
    int mine(1);
public:
    has_int(int v) { cout << "set: " << v << endl; mine = v; };
    has_int(has_int &h) { auto v = h.mine; cout << "copy: " << v << endl; mine = v; };
    void printme() { cout << "I have: " << mine << endl; };
};
```

Now if we define two functions, with the two parameter passing mechanisms, we see that passing by value invokes the copy constructor, and passing by const reference does not:

```cpp
void f_with_copy(has_int other) { cout << "function with copy" << endl; };
void f_with_ref(const has_int &other) { cout << "function with ref" << endl; };
/* ... */
cout << "Calling f with copy..." << endl;
f_with_copy(an_int);
cout << "Calling f with ref..." << endl;
f_with_ref(an_int);
```

Output
[const] constref:
Called function with copy
... done

We can make visible the difference between pass by value and pass by const-reference if we define a class where the *copy constructor* explicitly reports itself:

```cpp
class has_int {
private:
    int mine(1);
public:
    const int& int_to_get() { return mine; };
    int& int_to_set() { return mine; };
    void inc() { mine++; };
    /* ... */
    has_int an_int;
an_int.inc(); an_int.inc(); an_int.inc();
cout << "Contained int is now: "
    << an_int.int_to_get() << endl;
    /* Compiler error: an_int.int_to_get() = 5; */
an_int.int_to_set() = 17;
cout << "Contained int is now: "
    << an_int.int_to_get() << endl;
```

Output
[const] constref:
Contained int is now: 4
Contained int is now: 17

Introduction to Scientific Programming
18.2.1 Const references in range-based loops

The same pass by value/reference issue comes up in range-based for loops. The syntax

```
for ( auto v : some_vector )
```

copies the vector elements to the `v` variable, whereas

```
for ( auto& v : some_vector )
```

makes a reference. To get the benefits of references (no copy cost) while avoiding the pitfalls (inadvertant changes), you can also use a const-reference here:

```
for ( const auto& v : some_vector )
```

18.3 Const methods

We can distinguish two types of methods: those that alter internal data members of the object, and those that don’t. The ones that don’t can be marked `const`. While this is in no way required, it contributes to a clean programming style:

**Intention checking**

Using `const` will catch mismatches between the prototype and definition of the method. For instance,

```cpp
class Things {
    private:
        int var;
    public:
        f(int &ivar, int c) const {
            var += c; // typo: should be ‘ivar’
        }
}
```

Here, the use of `var` was a typo, should have been `ivar`. Since the method is marked `const`, the compiler will generate an error.

**No side-effects**

It encourages a functional style, in the sense that it makes *side-effects* impossible:

```cpp
class Things {
    private:
        int i;
    public:
        int get() const { return i; }
        int inc() { return i++; } // side-effect!
        void addto(int &thru) const { thru += i; }
}
```

18.4 Overloading on const

Victor Eijkhout
**Const polymorphism**

A const method and its non-const variant are different enough that you can use this for overloading.

**Code:**

```cpp
class has_array {
private:
    vector<float> values; 
public:
    has_array(int i, float v) :
        values((vector<float>({i,v}))) {};
    auto& at(int i) {
        cout << "var at" << endl;
        return values.at(i); }
    const auto& at(int i) const {
        cout << "const at" << endl;
        return values.at(i); }
    auto sum() const {
        float p; 
        for ( int i=0; i<values.size(); i++)
            p += at(i); 
        return p; 
    }
};

int main () {
    int l; float v; 
    cin >> l; cin >> v; 
    has_array fives(l,v); 
    cout << fives.sum() << endl;
    fives.at(0) = 2;
    cout << fives.sum() << endl;
}
```

**Output**

```plaintext
[const] constat:
const at
const at
const at
1.5
var at
const at
const at
const at
4.5
```

**Exercise 18.1.** Explore variations on this example, and see which ones work and which ones not.

1. Remove the second definition of `at`. Can you explain the error?
2. Remove either of the `const` keywords from the second `at` method. What errors do you get?

### 18.5 Const and pointers

Let’s declare a class `thing` to point to, and a class `has_thing` that contains a pointer to a `thing`.

**Code:**

```cpp
class thing {
private:
    int i;
public:
    thing(int i) : i(i) {};
    void set_value(int ii) { i = ii; };
    auto value() const { return i; };
};

class has_thing {
private:
    shared_ptr<thing> thing_ptr{nullopt};
public:
    has_thing(int i) : thing_ptr
```

**Introduction to Scientific Programming**
18.5. Const and pointers

If we define a method to return the pointer, we get a copy of the pointer, so redirecting that pointer has no effect on the container:

**Code:**

```cpp
auto get_thing_ptr() const {
    return thing_ptr;
}
/* ... */
has_thing container(5);
container.print();
container.get_thing_ptr() = 
    make_shared<thing>(6);
container.print();
```

**Output**

[const] constpoint2:

```
5
5
```

If we return the pointer by reference we can change it. However, this requires the method not to be const. On the other hand, with the const method earlier we can change the object:

**Code:**

```cpp
// Error: does not compile
// auto &get_thing_ptr() const {
auto &access_thing_ptr() {
    return thing_ptr;
}
/* ... */
has_thing container(5);
container.print();
container.access_thing_ptr() = 
    make_shared<thing>(7);
container.print();
container.get_thing_ptr()->set_value(8);
container.print();
```

**Output**

[const] constpoint3:

```
5
7
8
```

If you want to prevent the pointed object from being changed, you can declare the pointer as a `shared_ptr<const thing>`:

```cpp
private:
    shared_ptr<const thing> const_thing{nullptr};
public:
    has_thing(int i, int j)
    : const_thing{
        (make_shared<thing>(i+j)){};
    }
    auto get_const_ptr() const {
        return const_thing; }
    void print() const {
        cout << const_thing->value() << endl; }
    }/* ... */
has_thing container(1,2);
// Error: does not compile
container.get_const_ptr()->set_value(9);
```

18.5.1 Old-style const pointers

For completeness, a section on const and pointers in C.

We can have the `const` keyword in three places in the declaration of a C pointer:
18. Const

```
int *p;
const int *p;
int const * p; // this is the same
int * const p; // as this
```

For the interpretation, it is often said to read the declaration ‘from right to left’. So:

```
|| int * const p;
```

is a ‘const pointer to int’. This means that it is const what int it points to, but that int itself can change:

```
int i=5;
int * const ip = &i;
printf("ptr derefs to: %d",*ip);
*ip = 6;
printf("ptr derefs to: %d",*ip);
int j;
// DOES NOT COMPILE ip = &j;
```

On the other hand,

```
|| const int *p;
```

is a ‘pointer to a const int’. This means that you can point it at different ints, but you can not change the value those through the pointer:

```
const int * jp = &i;
i = 7;
printf("ptr derefs to: %d",*jp);
// DOES NOT COMPIL *jp = 8;
int k = 9;
jp = &k;
printf("ptr derefs to: %d",*jp);
```

Finally,

```
|| const int * const p;
```

is a ‘const pointer to const int’. This pointer can not be retargeted, and the value of its target can not be changed:

```
// DOES NOT WORK const int * const kp; kp = &k;
const int * const kp = &k;
printf("ptr derefs to: %d",*kp);
k = 10;
// DOES NOT COMPILE *kp = 11;
```

Because it can not be retargeted, you have to set its target when you declare such a pointer.

18.6 Mutable

Typical class with non-const update methods, and const readout of some computed quantity:
18.6. Mutable

class Stuff {
private:
  int i, j;
public:
  Stuff(int i, int j) : i(i), j(j) {};
  void seti(int inew) { i = inew; };
  void setj(int jnew) { j = jnew; };
  int result() const { return i+j; };
}

Attempt at caching the computation:
class Stuff {
private:
  int i, j;
  int cache;
  void compute_cache() { cache = i+j; };
public:
  Stuff(int i, int j) : i(i), j(j) {};
  void seti(int inew) { i = inew; compute_cache(); };
  void setj(int jnew) { j = jnew; compute_cache(); };
  int result() const { return cache; };
}

But what if setting happens way more often than getting?
class Stuff {
private:
  int i, j;
  int cache;
  bool cache_valid(false);
  void update_cache() const {
    if (!cache_valid) {
      cache = i+j; cache_valid = true;
    }
  }
public:
  Stuff(int i, int j) : i(i), j(j) {};
  void seti(int inew) { i = inew; cache_valid = false; };
  void setj(int jnew) { j = jnew; cache_valid = false; };
  int result() const { return cache; };
}

This does not compile, because result is const, but it calls a non-const function.
We can solve this by declaring the cache variables to be mutable. Then the methods that conceptually
don’t change the object can still stay const, even while altering the state of the object. (It is better not to
use const_cast.)
class Stuff {
private:
  int i, j;
  mutable int cache;
  mutable bool cache_valid(false);
  void update_cache() const {
    if (!cache_valid) {
      cache = i+j; cache_valid = true;
    }
  }
public:
  Stuff(int i, int j) : i(i), j(j) {};
}
18. Const

```cpp
void seti(int inew) { i = inew; cache_valid = false; };
void setj(int jnew) { j = jnew; cache_valid = false; }
int result () const {
    update_cache(); return cache; }
```

18.7 Compile-time constants

Compilers have long been able to simplify expressions that only contain constants:

```cpp
int i=5;
int j=i+4;
f(j)
```

Here the compiler will conclude that \( j \) is 9, and that’s where the story stops. It also becomes possible to let \( f(j) \) be evaluated by the compiler, if the function \( f \) is simple enough. C++17 added several more variants of constexpr usage.

The `const` keyword can be used to indicate that a variable can not be changed:

```cpp
const int i=5;
// DOES NOT COMPILE:
i += 2;
```

### Constexpr if

The combination `if constexpr` is useful with templates:

```cpp
template <typename T>
auto get_value(T t) {
    if constexpr (std::is_pointer_v<T>)
        return *t;
    else
        return t;
}
```

### Constant functions

To declare a function to be constant, use `constexpr`. The standard example is:

```cpp
constexpr double pi() {
    return 4.0 * atan(1.0); }
```

but also

```cpp
constexpr int factor(int n) {
    return n <= 1 ? 1 : (n*factor(n-1));
}
```

(Recursion in C++11, loops and local variables in C++14.)

- Can use conditionals, if testing on constant data;
- can use loops, if number of iterations constant;
- C++20 can allocate memory, if size constant.
Chapter 19

Prototypes and header files

19.1 Prototypes for functions

In most of the programs you have written in this course, you put any functions or classes above the main program, so that the compiler could inspect the definition before it encountered the use. However, the compiler does not actually need the whole definition, say of a function: it is enough to know its name, the types of the input parameters, and the return type.

Such a minimal specification of a function is known as function prototype; for instance

```c
int tester(float);
```

Prototypes and forward declarations, 1

A first use of prototypes is forward declaration.

Some people like defining functions after the main:

```c
int f(int);
int main() { 
    f(5);
};
int f(int i) { 
    return i;
}
```

versus before:

```c
int f(int i) { 
    return i;
}
int main() { 
    f(5);
};
```

Prototypes and forward declarations, 2

You also need forward declaration for mutually recursive functions:

```c
int f(int);
int g(int i) { return f(i); }
int f(int i) { return g(i); }
```

Prototypes are useful if you spread your program over multiple files. You would put your functions in one file and the main program in another.

```c
// file: def.cxx
int tester(float x) { 
    ..... 
}
```

```c
// file: main.cxx
int main() {
    int t = tester(...);
    return 0;
}
```
19. Prototypes and header files

In this example a function tester is defined in a different file from the main program, so we need to tell main what the function looks like in order for the main program to be compilable:

```cxx
// file: main.cxx
int tester(float);
int main() {
    int t = tester(...);
    return 0;
}
```

Splitting your code over multiple files and using separate compilation is good software engineering practice for a number of reasons.

1. If your code gets large, compiling only the necessary files cuts down on compilation time.
2. Your functions may be useful in other projects, by yourself or others, so you can reuse the code without cutting and pasting it between projects.
3. It makes it easier to search through a file without being distracted by unrelated bits of code.

(However, you would not do things like this in practice. See section 19.1.2 about header files.)

### 19.1.1 Separate compilation

#### Compiling and linking

Your regular compile line

```bash
icpc -o yourprogram yourfile.cc
```

actually does two things: compilation, and linking. You can do those separately:

1. First you compile

```bash
icpc -c yourfile.cc
```

which gives you a file `yourfile.o`, a so-called object file; and

2. Then you use the compiler as linker to give you the executable file:

```bash
icpc -o yourprogram yourfile.o
```

In this particular example you may wonder what the big deal is. That will become clear if you have multiple source files: now you invoke the compile line for each source, and you link them only once.

#### Dealing with multiple files

Compile each file separately, then link:

```bash
icpc -c mainfile.cc
icpc -c functionfile.cc
icpc -o yourprogram mainfile.o functionfile.o
```

At this point, you should learn about the Make tool for managing your programming project.
19.1.2 Header files

Even better than writing the prototype every time you need the function is to have a header file:

**Prototypes and header files**

```
// file: def.h
int tester(float);
```

The header file gets included both in the definitions file and the main program:

```
// file: def.cxx
#include "def.h"
int tester(float x) {
    ....
}

// file : main.cxx
#include "def.h"
int main() {
    int t = tester(...);
    return 0;
}
```

What happens if you leave out the `#include "def.h"` in both cases?

Having a header file is an important safety measure:

- Suppose you change your function definition, changing its return type:
- The compiler will complain when you compile the definitions file;
- So you change the prototype in the header file;
- Now the compiler will complain about the main program, so you edit that too.

It is necessary to include the header file in the main program. It is not strictly necessary to include it in the definitions file, but doing so means that you catch potential errors: if you change the function definitions, but forget to update the header file, this is caught by the compiler.

**Remark 12** By the way, why does that compiler even recompile the main program, even though it was not changed? Well, that’s because you used a makefile. See the tutorial.

**Remark 13** Header files were able to catch more errors in C than they do in C++. With polymorphism of functions, it is no longer an error to have

```
// header.h
int somefunction(int);
```

and

```
#include "header.h"
int somefunction( float x ) { .... }
```

19.1.3 C and C++ headers

You have seen the following syntaxes for including header files:

```
#include <header.h>
#include "header.h"
```
The first is typically used for system files, with the second typically for files in your own project. There are some header files that come from the C standard library such as math.h; the idiomatic way of including them in C++ is

```
#include <cmath>
```

### 19.2  Prototypes for class methods

#### Class prototypes

**Header file:**

```cpp
class something {
    private:
        int i;
    public:
        double dosomething(int i, char c);
};
```

**Implementation file:**

```cpp
double something::dosomething(int i, char c) {
    // do something with i,c
};
```

**Data members in proto**

Data members, even private ones, need to be in the header file:

```cpp
class something {
    private:
        int localVar;
    public:
        double somedo(vector);
};
```

**Implementation file:**

```cpp
double something::somedo(vector v) {
    .... something with v ....
    .... something with localVar ....
};
```

### Review 19.1  
For each of the following answer: is this a valid function definition or function prototype.

- `int foo();`
- `int foo() {};
- `int foo(int) {};
- `int foo(int bar) {};
- `int foo(int) { return 0; };
- `int foo(int bar) { return 0; };`
19.3 Header files and templates

The use of templates (see chapter 22) often make separate compilation hard: in order to compile the templated definitions the compiler needs to know with what types they will be used. For this reason, many libraries are header-only: they have to be included in each file where they are used, rather than compiled separately and linked.

In the common case where you can foresee with which types a templated class will be instantiated, there is a way out. Suppose you have a templated class:

```cpp
template<typename T>
class foo<T> {
};
```

and it will only be used (instantiated) with `float` and `double`, then adding the following lines after the class definition makes the file separately compilable:

```cpp
template class foo<float>;
template class foo<double>;
```

19.4 Namespaces and header files

Namespaces (see chapter 20) are convenient, but they carry a danger in that they may define functions without the user of the namespace being aware of it.

Therefore, one should never put `using namespace` in a header file.

19.5 Global variables and header files

If you have a variable that you want known everywhere, you can make it a global variable:

```cpp
int processnumber;
void f() {
    ... processnumber ...
}
int main() {
    processnumber = // some system call
};
```

It is then defined in the main program and any functions defined in your program file.

Warning: it is tempting to define variables global but this is a dangerous practice.

If your program has multiple files, you should not put `int processnumber` in the other files, because that would create a new variable, that is only known to the functions in that file. Instead use:

```cpp
extern int processnumber;
```

which says that the global variable `processnumber` is defined in some other file.

What happens if you put that variable in a header file? Since the preprocessor acts as if the header is textually inserted, this again leads to a separate global variable per file. The solution then is more complicated:
This sort of preprocessor magic is discussed in chapter 21.)

This also prevents recursive inclusion of header files.

19.6 Modules

The C++20 standard is taking a different approach to header files, through the introduction of modules. (Fortran90 already had this for a long time.) This largely dispenses with the need for header files included through C Preprocessor (CPP).
Chapter 20

Namespaces

20.1 Solving name conflicts

In section 11.3 you saw that the C++ STL comes with a vector class, that implements dynamic arrays. You say

```cpp
std::vector<int> bunch_of_ints;
```

and you have an object that can store a bunch of ints. And if you use such vectors often, you can save yourself some typing by having

```cpp
using namespace std;
```

somewhere high up in your file, and write

```cpp
vector<int> bunch_of_ints;
```

in the rest of the file.

More safe:

```cpp
using std::vector;
```

But what if you are writing a geometry package, which includes a vector class? Is there confusion with the STL vector class? There would be if it weren't for the phenomenon namespace, which acts as an disambiguating prefix for classes, functions, variables.

You have already seen namespaces in action when you wrote std::vector: the `std` is the name of the namespace.

**Defining a namespace**

You can make your own namespace by writing

```cpp
namespace a_namespace {
  // definitions
  class an_object {
  }
}
```

so that you can write
Namespace usage

```
|| a_namespace::an_object myobject();

or

|| using namespace a_namespace;
|| an_object myobject();

or

|| using a_namespace::an_object;
|| an_object myobject();

or

|| using namespace abc = space_a::space_b::space_c;
|| abc::func(x)
```

20.1.1 Namespace header files

If your namespace is going to be used in more than one program, you want to have it in a separate source file, with an accompanying header file:

```
#include "geolib.h"

using namespace geometry;
```

The header would contain the normal function and class headers, but now inside a named namespace:

```
namespace geometry {
    class point {
        private:
            double xcoord, ycoord;
        public:
            point() {};
            point( double x, double y );
            double x();
            double y();
        };
    class vector {
        private:
            point from, to;
        public:
            vector( point from, point to);
            double size();
    }
}
```

and the implementation file would have the implementations, in a namespace of the same name:

```
namespace geometry {
    point::point( double x, double y ) {
        xcoord = x; ycoord = y; }
    double point::x() { return xcoord; } // ‘accessor’
    double point::y() { return ycoord; }
    vector::vector( point from, point to) {
```
20.2 Best practices

In this course we advocated pulling in functions explicitly:

```cpp
#include <iostream>
using std::cout;
```

It is also possible to use

```cpp
#include <iostream>
using namespace std;
```

The problem with this is that it may pull in unwanted functions. For instance:

Why not `using namespace std`?

This compiles, but should not:  
```cpp
#include <iostream>
using namespace std;

def swop(int i, int j) {}

int main() {
    int i=1, j=2;
    swap(i, j);
    cout << i << endl;
    return 0;
}
```

This gives an error:

```cpp
#include <iostream>
using std::cout;
using std::endl;

def swop(int i, int j) {}

int main() {
    int i=1, j=2;
    swap(i, j);
    cout << i << endl;
    return 0;
}
```

Even if you use `using namespace`, you only do this in a source file, not in a header file. Anyone using the header would have no idea what functions are suddenly defined.

Victor Eijkhout
Chapter 21

Preprocessor

In your source files you have seen lines starting with a hash sign, like

```c
#include <iostream>
```

Such lines are interpreted by the C preprocessor.
We will see some of its more common uses here.

21.1 Include files

The `#include` pragma causes the named file to be included. That file is in fact an ordinary text file, stored somewhere in your system. As a result, your source file is transformed to another source file, in a source-to-source translation stage, and only that second file is actually compiled by the compiler.

Normally, this intermediate file with all included literally included is immediately destroyed again, but in rare cases you may want to dump it for debugging. See your compiler documentation for how to generate this file.

21.1.1 Kinds of includes

While you can include any kind of text file, normally you include a header file at the start of your source.

There are two kinds of includes

1. The file name can be included in angle brackets,

```c
#include <vector>
```

which is typically used for system headers that are part of the compiler infrastructure;

2. the name can also be in double quotes,

```c
#include "somelib.h"
```

which is typically used for files that are part of your code, or for libraries that you have downloaded and installed yourself.
21. Preprocessor

21.1.2 Search paths

System headers can usually be found by the compiler because they are in some standard location. Including other headers may require additional action by you. If you

```c
#include "foo.h"
```

the compiler only looks for that file in the current directory where you are compiling.

If the include file is part of a library that you have downloaded and installed yourself, say it is in

```
/home/yourname/mylibrary/include/foo.h
```

then you could of course

```c
#include "/home/yourname/mylibrary/include/foo.h"
```

but that does not make your code very portable to other systems and other users. So how do you make

```c
#include "foo.h"
```

be understood on any system?

The answer is that you can give your compiler one or more include paths. This is done with the `-I` flag.

```
icpc -c yourprogram.cxx -I/home/yourname/mylibrary/include
```

You can specify more than one such flag, and the compiler will try to find the `foo.h` file in all of them.

Are you now thinking that you have to type that path every time you compile? Now is the time to learn `makefiles` and the `Make` utility.

21.2 Textual substitution

Suppose your program has a number of arrays and loop bounds that are all identical. To make sure the same number is used, you can create a variable, and pass that to routines as necessary.

```c
void dosomething(int n) {
    for (int i=0; i<n; i++) ....
}
int main() {
    int n=100000;
    double array[n];
    dosomething(n);
}
```

You can also use `#define` to define a preprocessor macro:

```c
#define N 100000
void dosomething() {
    for (int i=0; i<N; i++) ....
}
```
int main() {
  double array[N];
  dosomething();
}

It is traditional to use all uppercase for such macros.

### 21.2.1 Dynamic definition of macros

Having numbers defined in the source takes away some flexibility. You can regain some of that flexibility by letting the macro be defined by the compiler, using the `-D` flag:

```bash
icpc -c yourprogram.cxx -DN=100000
```

Now what if you want a default value in your source, but optionally refine it with the compiler? You can solve this by testing for definition in the source with `#ifndef` ‘if not defined’:

```c
#ifndef N
#define N 10000
#endif
```

### 21.2.2 A new use for ‘using’

The `using` keyword that you saw in section 4.2 can also be used as a replacement for the `#typedef` pragma if it’s used to introduce synonyms for types.

```c
using Matrix = vector<vector<float>>;
```

### 21.2.3 Parametrized macros

Instead of simple text substitution, you can have *parametrized preprocessor macros*

```c
#define CHECK_FOR_ERROR(i) if (i!=0) return i
...
ierr = some_function(a,b,c); CHECK_FOR_ERROR(ierr);
```

When you introduce parameters, it’s a good idea to use lots of parentheses:

```c
// the next definition is bad!
#define MULTIPLY(a,b) a*b
...
x = MULTIPLY(1+2,3+4);
```

Better

```c
#define MULTIPLY(a,b) (a)*(b)
...
x = MULTIPLY(1+2,3+4);
```

Another popular use of macros is to simulate multi-dimensional indexing:
## 21. Preprocessor

```c
#define INDEX2D(i,j,n) (i)*(n)+j
...
double array[m,n];
for (int i=0; i<m; i++)
  for (int j=0; j<n; j++)
    array[INDEX2D(i,j,n)] = ...
```

### Exercise 21.1. Write a macro that simulates 1-based indexing:

```c
#define INDEX2D1BASED(i,j,n) ???
...
double array[m,n];
for (int i=1; i<=m; i++)
  for (int j=n; j<=n; j++)
    array[INDEX2D1BASED(i,j,n)] = ...
```

## 21.3 Conditionals

There are a couple of preprocessor conditions.

### 21.3.1 Check on a value

The `#if` macro tests on nonzero. A common application is to temporarily remove code from compilation:

```c
#if 0
  bunch of code that needs to be disabled
#endif
```

### 21.3.2 Check for macros

The `#ifdef` test tests for a macro being defined. Conversely, `#ifndef` tests for a macro not being defined. For instance,

```c
#ifndef N
#define N 100
#endif
```

Why would a macro already be defined? Well you can do that on the compile line:

```
icpc -c file.cc -DN=500
```

Another application for this test is in preventing recursive inclusion of header files; see section 19.5.
21.3.3 Including a file only once

It is easy to wind up including a file such as `iostream` more than once, if it is included in multiple other header files. This adds to your compilation time, or may lead to subtle problems. A header file may even circularly include itself. To prevent this, header files often have a structure

```c
// this is foo.h
#ifndef FOO_H
#define FOO_H
// the things that you want to include
#endif
```

Now the file will effectively be included only once: the second time it is included its content is skipped. Many compilers support the pragma `#once` (which, however, is not a language standard) that has the same effect:

```c
// this is foo.h
#pragma once
// the things you want to include only once
```

21.4 Other pragmas

- Packing data structure without padding bytes by `#pack`

```c
#pragma pack(push, 1)
// data structures
#pragma pack(pop)
```

If you have too many `#ifdef` cases, you may get combinations that don’t work. There is a convenient pragma to exit compilations that don’t make sense: `#error`.

```c
#error __vax__
#error "Won’t work on VAXen."
@endef
```
21. Preprocessor
Chapter 22

Templates

Sometimes you want a function or a class based on more than one different datatypes. For instance, in chapter 11 you saw how you could create an array of ints as `vector<int>` and of doubles as `vector<double>`. Here you will learn the mechanism for that.

**Templated type name**

If you have multiple routines that do ‘the same’ for multiple types, you want the type name to be a variable. Syntax:

```cpp
template <typename yourtypevariable>
// ... stuff with yourtypevariable ...
```

Historically `typename` was `class` but that’s confusing.

### 22.1 Templated functions

**Example: function**

**Definition:**

```cpp
template<typename T>
void function(T var) { cout << var << end; }
```

**Usage:**

```cpp
int i; function(i);
double x; function(x);
```

and the code will behave as if you had defined `function` twice, once for `int` and once for `double`.

**Exercise 22.1.** Machine precision, or ‘machine epsilon’, is sometimes defined as the smallest number $\epsilon$ so that $1 + \epsilon > 1$ in computer arithmetic.

Write a templated function `epsilon` so that the following code prints out the values of the machine precision for the `float` and `double` type respectively:
22. Templates

```cpp
float float_eps;
epsilon(float_eps);
cout << "Epsilon float: "
    << setw(10) << setprecision(4)
    << float_eps << endl;

double double_eps;
epsilon(double_eps);
cout << "Epsilon double: "
    << setw(10) << setprecision(4)
    << double_eps << endl;
```

Output

<table>
<thead>
<tr>
<th>template eps:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Epsilon float: 1.0000e-07</td>
</tr>
<tr>
<td>Epsilon double: 1.0000e-15</td>
</tr>
</tbody>
</table>

22.2 Templated classes

The most common use of templates is probably to define templated classes. You have in fact seen this mechanism in action:

**Templated vector**

The STL contains in effect

```cpp
template<typename T>
class vector {
private:
    T *vectordata; // internal data
public:
    T at(int i) { return vectordata[i] }; 
    int size() { /* return size of data */ }; 
    // much more
};
```

22.2.1 Specific implementation

```cpp
template<typename T>
void f(T);
template <>
void f(char c) { /* code with c */ }; 
template <>
void f(double d) { /* code with d */ }; 
```

22.3 Example

Let’s start with a simple class for polynomials:

```cpp
class polynomial {
private:
    vector<double> coefficients;
public:
    polynomial( vector<double> c )
```
22.3. Example

```cpp
// 5 x^2 + 4 x + 3 = 5 x + 4 x + 3
double eval( double x ) const {
    double y(0.);
    for_each(coefficients.rbegin(),coefficients.rend(),
             [x,&y] (double c) { y *= x; y += c; });
    return y;
}

double operator()(double x) const { return eval(x); }
```

We store the polynomial coefficients, with the zeroth-degree coefficient in location zero, et cetera. The routine for evaluating a polynomial for a given input \( x \) is an implementation of Horner’s scheme:

\[
5x^2 + 4x + 3 \equiv ((5 \cdot x + 4) \cdot x + 3
\]

This class is used as:

```cpp
class polynomial x2p2( {2., 0., 1.} );
for ( auto x : {1., 2., 3.} ) {
    auto y = x2p2(x);
    cout << "Second power of x=" << x << " plus 2 gives y=" << y << "\n";
}
```

You may know from mathematics courses that you can also have polynomials based on square matrices. In that case, all matrix coefficients, as well as the \( x \) input and \( y \) output, are matrices.

The above code for evaluating a polynomial for a certain input works just as well for matrices, as long as the multiplication and addition operator are defined. So let’s say we have a class `mat` and we have

```cpp
mat::mat operator+( const mat& other ) const;
void mat::operator+=( const mat& other );
mat::mat operator*( const mat& other ) const;
void mat::operator*=( const mat& other );
```

Now we define the `polynomial` class as templated over the scalar type:

```cpp
template< typename Scalar >
class polynomial {
public:
    vector<Scalar> coefficients;
    polynomial( vector<Scalar> c ) :
        coefficients(c) {};
    int degree() const { return coefficients.size()-1; };
    // 5 x^2 + 4 x + 3 = 5 x + 4 x + 3
    Scalar eval( Scalar x ) const {
        Scalar y(0.);
        for_each(coefficients.rbegin(),coefficients.rend(),
                  [x,&y] (Scalar c) { y *= x; y += c; });
        return y;
    }
};
```

The code using polynomials stays the same, except that we have to supply the scalar type as template parameter whenever we create a polynomial object. For scalars:

```cpp
class polynomial( vector<double> c ) :
    coefficients(c) {};
```
22. Templates

```cpp
polynomial<double> x2p2({2., 0., 1.});
for (auto x : {1., 2., 3.}) {
    auto y = x2p2(x);
    cout << "Second power of x= " << x << " plus 2 gives y= " << y << "\n";
}
```

and for matrices:

```cpp
polynomial<mat> x2p2({2., 0., 1.});
for (auto x : {1., 2., 3.}) {
    auto y = x2p2(x);
    cout << "Second power of x= " << x << " plus 2 gives y= " << y << "\n";
}
```

22.4 Concepts

Coming in the C++20 standard.

Templates can be too generic. For instance, one could write a templated \texttt{gcd} function

```cpp
template<typename T>
T gcd(T a, T b) {
    if (b==0) return a;
    else return gcd(b, a%b);
}
```

which will work for various integral types. To prevent it being applied to non-integral types, you can specify a \texttt{concept} to the type:

```cpp
template<typename T>
concept bool Integral() { return std::is_integral<T>::value;
}
```

used as:

```cpp
template<typename T>
requires Integral<T>()
T gcd(T a, T b) { /* ... */ }
```

or

```cpp
template<Integral T>
T gcd(T a, T b) { /* ... */ }
```

Abbreviated function templates:

```cpp
Integral auto gcd
    ( Integral auto a, Integral auto b )
    { /* ... */ }
```
23.1 General discussion

When you’re programming, making errors is close to inevitable. Syntax errors, violations of the grammar of the language, will be caught by the compiler, and prevent generation of an executable. In this section we will therefore talk about runtime errors: behaviour at runtime that is other than intended.

Here are some sources of runtime errors

Array indexing  Using an index outside the array bounds may give a runtime error:

```
vector<float> a(10);
for (int i=0; i<=10; i++)
a.at(i) = x; // runtime error
```

or undefined behaviour:

```
vector<float> a(10);
for (int i=0; i<=10; i++)
a[i] = x;
```

See further section 11.3.

Null pointers  Using an uninitialized pointer is likely to crash your program:

```
Object *x;
if (false) x = new Object;
```

Numerical errors  such as division by zero will not crash your program, so catching them takes some care.

Guarding against errors.

• Check preconditions.
• Catch results.
• Check postconditions.

Error reporting:

• Message
• Total abort
• Exception
23. Error handling

23.2 Mechanisms to support error handling and debugging

23.2.1 Assertions

One way catch errors before they happen, is to sprinkle your code with assertions: statements about things that have to be true. For instance, if a function should mathematically always return a positive result, it may be a good idea to check for that anyway. You do this by using the `assert` command, which takes a boolean, and will stop your program if the boolean is false:

```cpp
#include <cassert>
float positive_outcome = f(x, y, z);
assert( positive_outcome > 0 );
```

Since checking an assertion is a minor computation, you may want to disable it when you run your program in production by defining the `NDEBUG` macro:

```cpp
#define NDEBUG
```

One way of doing that is passing it as a compiler flag:

```sh
icpc -DNDEBUG yourprog.cxx
```

Function return values

23.2.2 Exception handling

23.2.2.1 Exception catching

During the run of your program, an error condition may occur, such as accessing a vector elements outside the bounds of that vector, that will make your program stop. You may see text on your screen terminating with uncaught exception

The operative word here is exception: an exceptional situation that caused the normal program flow to have been interrupted. We say that your program throws an exception.

```
Code:
vector<float> x(5);
x.at(5) = 3.14;
```

```
Output
[except] boundthrow:
```

Now you know that there is an error in your program, but you don’t know where it occurs. You can find out, but trying to catch the exception.
23.2. Mechanisms to support error handling and debugging

Code:

```cpp
vector<float> x(5);
for (int i=0; i<10; i++) {
    try {
        x.at(i) = 3.14;
    } catch (...) {
        cout << "Exception indexing at: "
             << i << endl;
        break;
    }
}
```

Output

[except] boundcatch:

23.2.2.2 Popular exceptions

- `std::out_of_range`: usually caused by using `at` with an invalid index.

23.2.2.3 Throw your own exceptions

**Exception throwing**

Throwing an exception is one way of signalling an error or unexpected behaviour:

```cpp
void do_something() {
    if (oops)
        throw(5);
}
```

**Catching an exception**

It now becomes possible to detect this unexpected behaviour by catching the exception:

```cpp
try {
    do_something();
} catch (int i) {
    cout << "doing something failed: error= " << i << endl;
}
```

If you’re doing the prime numbers project, you can now do exercise 52.12.

You can throw integers to indicate an error code, a string with an actual error message. You could even make an error class:

**Exception classes**

```cpp
class MyError {
public:
    int error_no; string error_msg;
    MyError( int i, string msg )
        : error_no(i), error_msg(msg) {};

    throw( MyError(27,"oops");
}
try {
    // something
}
```

Victor Eijkhout 235
You can use exception inheritance!

Multiple catches

You can multiple catch statements to catch different types of errors:

```cpp
try {
    // something
} catch (int i) {
    // handle int exception
} catch (std::string c) {
    // handle string exception
}
```

Catch any exception

Catch exceptions without specifying the type:

```cpp
try {
    // something
} catch (...) { // literally: three dots
    cout << "Something went wrong!" << endl;
}
```

Exercise 23.1. Define the function

\[ f(x) = x^3 - 19x^2 + 79x + 100 \]

and evaluate \( \sqrt{f(i)} \) for the integers \( i = 0 \ldots 20 \).

- First write the program naively, and print out the root. Where is \( f(i) \) negative? What does your program print?
- You see that floating point errors such as the root of a negative number do not make your program crash or something like that. Alter your program to throw an exception if \( f(i) \) is negative, catch the exception, and print an error message.
- Alter your program to test the output of the \texttt{sqrt} call, rather than its input. Use the function \texttt{isnan}

```cpp
#include <cfenv>
using std::isnan;
```

and again throw an exception.

Exceptions in constructors

A function try block will catch exceptions, including in initializer lists of constructors.

```cpp
f::f( int i )
try : fbase(i) {
    // constructor body
}
```
23.2. Mechanisms to support error handling and debugging

```c
} catch (...) { // handle exception
}
```

More about exceptions

- Functions can define what exceptions they throw:
  ```c
  void func() throw(MyError, std::string);
  void funk() throw();
  ```
- Predefined exceptions: `bad_alloc`, `bad_exception`, etc.
- An exception handler can throw an exception; to rethrow the same exception use `throw;` without arguments.
- Exceptions delete all stack data, but not `new` data. Also, destructors are called; section 10.4.9.
- There is an implicit `try/except` block around your main. You can replace the handler for that. See the `exception` header file.
- Keyword `noexcept`:
  ```c
  void f() noexcept { ... };
  ```
- There is no exception thrown when dereferencing a `nullptr`.

23.2.3 ‘Where does this error come from’

The CPP defines two macros, `__FILE__` and `__LINE__` that give you respectively the current file name and the current line number. You can use these to generate pretty error messages such as

```
Overflow occurred in line 25 of file numerics.cxx
```

The C++20 standard will offer `std::source_location` as a mechanism instead.

23.2.4 Legacy mechanisms

The traditional approach to error checking is for each routine to return an integer parameter that indicates success or absence thereof. Problems with this approach arise if it’s used inconsistently, for instance by a user forgetting to heed the return codes of a library. Also, it requires that every level of the function calling hierarchy needs to check return codes.

The PETSc library uses this mechanism consistently throughout, and to great effect.

Exceptions are a better mechanism, since
- they can not be ignored, and
- they do not require handling on the levels of the calling hierarchy between where the exception is thrown and where it is caught.

And then there is the fact that memory management is automatic with exceptions.

23.2.5 Legacy C mechanisms

The `errno` variable and the `setjmp` / `longjmp` functions should not be used. These functions for instance do not the memory management advantages of exceptions.
23. Error handling

23.3 Tools

Despite all your careful programming, your code may still compute the wrong result or crash with strange errors. There are two tools that may then be of assistance:

- `gdb` is the GNU interactive debugger. With it, you can run your code step-by-step, inspecting variables along the way, and detecting various conditions. It also allows you to inspect variables after your code throws an error.
- `valgrind` is a memory testing tool. It can detect memory leaks, as well as the use of uninitialized data.
Chapter 24

Standard Template Library

The C++ language has a Standard Template Library (STL), which contains functionality that is considered standard, but that is actually implemented in terms of already existing language mechanisms. The STL is enormous, so we just highlight a couple of parts.

You have already seen
- arrays (chapter 11),
- strings (chapter 12),
- streams (chapter 13).

Using a template class typically involves

```cpp
#include <something>
using std::function;
```

see section 20.1.

24.1 Complex numbers

Complex numbers require the `complex` header. The `complex` type uses templating to set the precision.

```cpp
#include <complex>
complex<float> f;
  f.re = 1.; f.im = 2.;
complex<double> d(1.,3.);
```

Math operator like +, * are defined, as are math functions such as `exp`.

Imaginary unit number `i` through literals `i`, `if` (float), `il` (long):

```cpp
using namespace std::complex_literals;
std::complex<double> c = 1.0 + il;
```

Support:

```cpp
std::complex<T> conj( const std::complex<T>& z );
std::complex<T> exp( const std::complex<T>& z );
```
24. Standard Template Library

24.2 Containers

Vectors (section 11.3) and strings (chapter 12) are special cases of a STL container. Methods such as push_back and insert apply to all containers.

24.2.1 Maps: associative arrays

Arrays use an integer-valued index. Sometimes you may wish to use an index that is not ordered, or for which the ordering is not relevant. A common example is looking up information by string, such as finding the age of a person, given their name. This is sometimes called ‘indexing by content’, and the data structure that supports this is formally known as an associative array.

In C++ this is implemented through a map:

```cpp
#include <map>
using std::map;
map<string, int> ages;
```

is set of pairs where the first item (which is used for indexing) is of type string, and the second item (which is found) is of type int.

A map is made by inserting the elements one-by-one:

```cpp
#include <map>
using std::make_pair;
ages.insert(make_pair("Alice",29));
ages["Bob"] = 32;
```

You can range over a map:

```cpp
for ( auto person : ages )
    cout << person.first << " has age " << person.second << endl;
```

A more elegant solution uses structured bindings (section 24.4):

```cpp
for ( auto [person,age] : ages )
    cout << person << " has age " << age << endl;
```

Searching for a key gives either the iterator of the key/value pair, or the end iterator if not found:

```cpp
for ( auto k : {4,5} ) {
    auto wherek = intcount.find(k);
    if ( wherek==intcount.end() )
        cout << "could not find key" << k << endl;
    else {
        auto [kk,vk] = *wherek;
        cout << "found key: " << kk << " has value " << vk << endl;
    }
}
```

Exercise 24.1. If you’re doing the prime number project, you can now do the exercises in section 52.7.2.
24.2. Containers

24.2.2 Iterators

The container class has a subclass iterator that can be used to iterate through all elements of a container. This was discussed in section 11.8.1.

However, an iterator can be used outside of strictly iterating. References to begin and end are common.

**Iterators outside a loop**

First, you can use them by themselves:

```cpp
vector<int> v{1,3,5,7};
auto pointer = v.begin();
cout << "we start at "
    << *pointer << endl;
pointer++;
cout << "after increment: "
    << *pointer << endl;

pointer = v.end();
cout << "end is not a valid element: "
    << *pointer << endl;
pointer--;
cout << "last element: "
    << *pointer << endl;
```

(Note: the auto actually stands for vector::iterator)

Output

| [stl iter: | we start at 1 | after increment: 3 | end is not a valid element: 0 | last element: 7 |

Note that the star notation is an operator, not a pointer dereference:

```cpp
vector<int> vec{11,22,33,44,55,66};
auto second = vec.begin(); second++;
cout << "Dereference second: "
    << *second << endl;
// DOES NOT COMPILE
// the iterator is not a type-star:
// int *subarray = second;
```

24.2.2.1 Vector methods using iterators

Vector methods such as erase and insert use these iterators:

**Iterators in vector methods**

Methods erase and insert indicate their range with begin/end iterators
24. Standard Template Library

### 24.2.2.2 Indexing and iterating

One of the arguments for range-based indexing was that we get a simple syntax if we don’t need the index. Is it possible to use iterators and still get the index? Yes, that’s what the function `distance` is for.

#### Code:

```cpp
vector<int> numbers{1,3,5,7,9};
auto it=numbers.begin();
while (it!=numbers.end()) {
    auto d = distance(numbers.begin(),it);
    cout << "At distance " << d << " we find "
         "it" << endl;
    it++;
}
```

#### Output [loop] distance:

At distance 0 we find 1  
At distance 1 we find 3  
At distance 2 we find 5  
At distance 3 we find 7  
At distance 4 we find 9

#### 24.2.2.3 Algorithms using iterators

Numerical reductions can be applied using iterators:

### Reduction operation

Default is sum reduction:

#### Code:

```cpp
vector<int> v{1,3,5,7,9};
auto first = v.begin();
auto last = v.end();
auto sum = accumulate(first,last,0);
cout << "sum: " << sum << endl;
```

#### Output [stl] accumulate:

sum: 16

Supply multiply operator:
Max reduction

Specific for the max reduction is `max_element`. This can be called without a comparator (for numerical max), or with a comparator for general maximum operations.

Example: maximum relative deviation from a quantity:

```cpp
max_element(myvalue.begin(), myvalue.end(),
            [my_sum_of_squares] (double x, double y) -> bool {
              return fabs((my_sum_of_squares-x)/x) < fabs((my_sum_of_squares-y)/y); })
```

24.2.2.4 Forming sub-arrays

Iterators can be used to construct a `vector`. This can for instance be used to create a subvector:
24. Standard Template Library

24.3 Regular expression

The header regex gives C++ the functionality for regular expression matching. For instance, `regex_match` returns whether or not a string matches an expression exactly:

```cpp
Code:
vector<string> names {"Victor", "aDam", "DoD"};
auto cap = regex("[A-Z][a-z]+" );
for ( auto n : names ) {
    auto match = regex_match( n, cap );
    if (match) cout << " : yes";  
    else cout << " : no" ;
    cout << endl;
}
```

(Note that the regex matches substrings, but `regex_match` only returns true for a match on the whole string.

For finding substrings, use `regex_search`:

- the function itself evaluates to a `bool`;
- there is an optional return parameter of type `smatch` (‘string match’) with information about the match.

The `smatch` object has these methods:

- `smatch::position` states where the expression was matched,
- `while smatch::str` returns the string that was matched.
- `smatch::prefix` has the string preceeding the match; with `smatch::prefix().size()` you get the number of characters preceeding the match, that is, the location of the match.

```cpp
Output
[regexp] regexp:
Looks like a name:
libc++abi.dylib: terminating with uncaught exception of type std::__1::regex_error: Unknown error type
```

```cpp
Output
[regexp] search:
Found <<the>>
Found <<o[ˆo]+o>> at 12 as <<ow fo>> preceded by <<The quick br>>
```

Introduction to Scientific Programming
24.3.1 Regular expression syntax

If your regular expression is getting too complicated with escape characters and such, consider using the *raw string literal* construct.

24.4 Tuples and structured bindings

Remember how in section 7.4.2 we said that if you wanted to return more than one value, you could not do that through a return value, and had to use an *output parameter*? Well, using the STL there is a different solution.

You can make a *tuple*: an entity that comprises several components, possibly of different type, and which unlike a *struct* you do not need to define beforehand.

**C++11 style tuples**

```cpp
std::tuple<int, double> id = std::make_tuple<int, double>(3, 5.12);
double result = std::get<1>(id);
std::get<0>(id) += 1;
```

This does not look terribly elegant. Fortunately, C++17 can use denotations and the *auto* keyword to make this considerably shorter. Consider the case of a function that returns a tuple. You could use *auto* to deduce the return type:

```cpp
auto maybe_root1(float x) {
    if (x<0)
        return make_tuple<bool, float>(false, -1);
    else
        return make_tuple<bool, float>(true, sqrt(x));
}
```

but more interestingly, you can use a *tuple denotation*:

```cpp
tuple<bool, float>
maybe_root2(float x) {
    if (x<0)
        return (false, -1);
    else
        return (true, sqrt(x));
}
```

**Catching a returned tuple**

The calling code is particularly elegant:
24. Standard Template Library

Code:

```cpp
class auto [succeed, y] = maybe_root2(x);
if (succeed)
    cout << "Root of " << x
        << " is " << y % endl;
else
    cout << "Sorry, " << x
        << " is negative" << endl;
```

Output [stl] tuple:

Root of 2 is 1.41421
Sorry, -2 is negative

This is known as structured binding.

An interesting use of structured bindings is iterating over a map (section 24.2.1):

```cpp```
```cpp
for (const auto &[key, value] : mymap) ....
```
```
```

24.5 Union-like stuff: tuples, optionals, variants

There are cases where you need a value that is one type or another, for instance, a number if a computation succeeded, and an error indicator if not.

The simplest solution is to have a function that returns both a bool and a number:

```cpp```
```cpp
bool RootOrError(float &x) {
    if (x<0)
        return false;
    else
        return sqrt(x);
}
```
```
```

An interesting use of structured bindings is iterating over a map (section 24.2.1):

```cpp```
```cpp
for (auto x : {2.f,-2.f})
    RootOrError(x);
```
```
```

We will now consider some more idiomatically C++17 solutions to this.

24.5.1 Tuples

Using tuples (section 24.4) the solution to the above ‘a number or an error’ now becomes:

```cpp```
```cpp
tuple<1 bool, float> RootAndValid(float x) {
    if (x<0)
        return {false, x};
    else
        return {true, sqrt(x)};
};
```
```
```

```cpp```
```cpp
for (auto x : {2.f,-2.f})
    RootAndValid(x);
```
```
```

Introduction to Scientific Programming
24.5. Union-like stuff: tuples, optionals, variants

24.5.2 Optional

The most elegant solution to ‘a number or an error’ is to have a single quantity that you can query whether it’s valid. For this, the C++17 standard introduced the concept of a nullable type: a type that can somehow convey that it’s empty.

Here we discuss `std::optional`.

```
#include <optional>
using std::optional;
```

- You can create an optional quantity with a function that returns either a value of the indicated type, or `{}`, which is a synonym for `nullopt`.
  ```
  optional<float> f {
    if (something) return 3.14;
    else return {};
  }
  ```

- You can test whether the optional quantity has a quantity with `has_value`, in which case you can extract the quantity with `value`:
  ```
  auto maybe_x = f();
  if (f.has_value)
    // do something with f.value();
  ```

There is a function `value_or` that gives the value, or a default if the optional did not have a value.

**Exercise 24.2.** You can now do exercise 52.15.

24.5.3 Variant

In C, a union is an entity that can be one of a number of types. Just like that C arrays do not know their size, a union does not know what type it is. The C++ variant does not suffer from these limitations. The function `get_if` can retrieve a value by type.

Let’s start with a variant of int, double, string:

```
variant<int, double, string> union_ids;
```

We can use the `index` function to see what variant is used (0,1,2 in this case) and get the value accordingly:

```
union_ids = 3.5;
switch (union_ids.index()) {
  case 1 :
    cout << "Double case: " << std::get<double>(union_ids) << endl;
  }
```

Getting the wrong variant leads to a bad_variant_access exception:

```
union_ids = 17;
cout << "Using option " << union_ids.index() << ": " << get<int>(union_ids) << endl;
try {
  cout << "Get as double: " << get<double>(union_ids) << endl;
```
24. Standard Template Library

```cpp
} catch (bad_variant_access b) {
    cout << "Exception getting as double while index=" << union_ids.index() << endl;
}
```

It is safer to use `get_if` which gives a pointer if successful, and false if not:

```cpp
union_ids = "Hello world";
if ( auto union_int = get_if<int>(&union_ids); union_int )
    cout << "Int: " << *union_int << endl;
else if ( auto union_string = get_if<string>(&union_ids); union_string )
    cout << "String: " << *union_string << endl;
```

Note that this needs the address of the variant, and returns something that you need to dereference.

Exercise 24.3. Write a routine that computes the roots of the quadratic equation

\[ ax^2 + bx + c = 0. \]

The routine should return two roots, or one root, or an indication that the equation has no solutions.

In this exercise you can return a boolean to indicate ‘no roots’, but a boolean can have two values, and only one has meaning. For such cases there is `std::monostate`.

24.5.3.1 The same function on all variants

Suppose you have a variant of some classes, which all support an identically prototyped method:

```cpp
class x_type {
    public: r_type method() { ... ;
};
class y_type {
    public: r_type method() { ... ;
}
```

It is not directly possible to call this method on a variant:

```cpp
variant< x_type, y_type> xy;
// WRONG xy.method();
```

For a specific example:

```cpp
variant<double_object,string_object>
    union_is_double( double_object(2.5) ),
    union_is_string( string("two-point-five") );
```

where we have methods `stringer` that gives a string representation, and `sizer` that gives the ‘size’ of the object.

The solution for this is `std::visit`, coming from the `variant` header. This is used to apply an object (defined below) to the variant object:
24.6. Limits

The mechanism to realize this is to have an object (here `stringer` and `sizer`) with an overloaded `operator()`. One implementation:

```cpp
class sizer {
public:
    int operator() (double_object d) {
        return static_cast<int>(d.value());
    }
    int operator() (string_object s) {
        return s.value().size();
    }
};
```

24.5.4 Any

While `variant` can be any of a number of prespecified types, `std::any` can contain really any type. Thus it is the equivalent of `void*` in C.

An `any` object can be cast with `any_cast`:

```cpp
std::any a{12};
std::any_cast<int>(a); // succeeds
std::any_cast<string>(a); // fails
```

24.6 Limits

There used to be a header file `limits.h` that contained macros such as `MAX_INT`. While this is still available, the STL offers a better solution in the `numeric_limits` header.

**Templated functions for limits**

Use header file `limits`:

```cpp
#include <limits>
using std::numeric_limits;

cout << numeric_limits<long>::max();
```

**Some limit values**
24. Standard Template Library

Code:

```cpp
# include <numeric>

int main()
{
    cout << "Signed int: "
         << numeric_limits<int>::min() << " "
         << numeric_limits<int>::max() << endl;
    cout << "Unsigned "
         << numeric_limits<unsigned int>::min() << " "
         << numeric_limits<unsigned int>::max() << endl;
    cout << "Single "
         << numeric_limits<float>::min() << " "
         << numeric_limits<float>::max() << endl;
    cout << "Double "
         << numeric_limits<double>::min() << " "
         << numeric_limits<double>::max() << endl;
    return 0;
}
```

Output

```plaintext

[stl limits]:
Signed int: -2147483648 2147483647
Unsigned 0 4294967295
Single 1.17549e-38 3.40282e+38
Double 2.22507e-308 1.79769e+308
```

Limits of floating point values

- `min` is the smallest positive number;
- use `lowest` for ‘most negative’.
- There is an `epsilon` function for machine precision:

Code:

```cpp
# include <numeric>

int main()
{
    cout << "Single lowest "
         << numeric_limits<float>::lowest() << " and epsilon "
         << numeric_limits<float>::epsilon() << endl;
    cout << "Double lowest "
         << numeric_limits<double>::lowest() << " and epsilon "
         << numeric_limits<double>::epsilon() << endl;
    return 0;
}
```

Output

```plaintext

[stl eps]:
Single lowest -3.40282e+38 and epsilon 1.19209e-07
Double lowest -1.79769e+308 and epsilon 2.22045e-16
```

Exercise 24.4. Write a program to discover what the maximal $n$ is so that $n!$, that is, $n$-factorial, can be represented in an `int`, `long`, or `long long`. Can you write this as a templated function?

Operations such as dividing by zero lead to floating point numbers that do not have a valid value. For efficiency of computation, the processor will compute with these as if they are any other floating point number.

There are tests for detecting whether a number is `Inf` or `NaN`. However, using these may slow a computation down.

**Detection of Inf and NaN**

The functions `isinf` and `isnan` are defined for the floating point types (`float`, `double`, `long double`), returning a `bool`.

Introduction to Scientific Programming
24.7. Common numbers

```c
#include <math.h>

isnan(-1.0/0.0); // false
isnan(sqrt(-1.0)); // true
isinf(-1.0/0.0); // true
isinf(sqrt(-1.0)); // false
```

24.6.1 Storage

- An `int` used to be 16 bits in the olden days, but these days 32 bits is more common.
- A long int `long` has at least the range of an `int`, and at least 32 bits.
- A long long int `long long` has at least the range of a `long`, and at least 64 bits.

24.7 Common numbers

```c
#include <numbers>

static constexpr float pi = std::numbers::pi;
```

24.8 Random numbers

The STL has a random number generator that is more general and more flexible than the C version (section 7.8.1).

- There are several generators that give uniformly distributed numbers;
- then there are distributions that translate this to non-uniform or discrete distributions.

First you declare an engine; later this will be transformed into a distribution:

```c
std::default_random_engine generator;
```

This generator will start at the same value everytime. You can seed it:

```c
std::random_device r;
std::default_random_engine generator{ r() };
```

Next, you need to declare the distribution. For instance, a uniform distribution between given bounds:

```c
std::uniform_real_distribution<float> distribution(0.,1.);
```

A roll of the dice would result from:

```c
std::uniform_int_distribution<int> distribution(1,6);
```

Random floats

```c
// seed the generator
std::random_device r;
// std::seed_seq ssq{r()};
// and then passing it to the engine does the same

// set the default random number generator
std::default_random_engine generator{r()};

// distribution: real between 0 and 1
std::uniform_real_distribution<float> distribution(0.,1.);
```
```cpp
cout << "first rand: " << distribution(generator) << endl;
```

### Dice throw

// set the default generator
std::default_random_engine generator;

// distribution: ints 1..6
std::uniform_int_distribution<int> distribution(1, 6);

// apply distribution to generator:
int dice_roll = distribution(generator);
// generates number in the range 1..6

### Poisson distribution

Another distribution is the Poisson distribution:

```cpp
std::default_random_engine generator;
float mean = 3.5;
std::poisson_distribution<int> distribution(mean);
int number = distribution(generator);
```

## 24.9 Time

### Header

```cpp
#include <chrono>
```

Several clocks. Here we use

```cpp
using myclock = std::chrono::high_resolution_clock;
```

### Resolution:

```cpp
auto num = myclock::period::num,
    den = myclock::period::den;
auto tick = static_cast<double>(num)/static_cast<double>(den);
```

### Timing:

```cpp
auto start_time = myclock::now();
auto duration = myclock::now()-start_time;
auto microsec_duration =
    std::chrono::duration_cast<std::chrono::microseconds>(duration);
cout << "This took " << microsec_duration.count() << "usec" << endl;
```

### Computing new time points:

```cpp
auto deadline = myclock.now() + std::chrono::seconds(10);
```
24.10 File system
As of the C++17 standard, there is a file system header, `filesystem`, which includes things like a directory walker.

```cpp
#include <filesystem>
```

24.11 Regular expressions

**Example**

```cpp
vector<string> names { "Victor", "aDam", "DoD" };
auto cap = regex("[A-Z][a-z]+\"\n");
for ( auto n : names ) {
    auto match = regex_match( n, cap );
    cout << n;
    if (match) cout << ": yes\n";
    else cout << ": no\n";
    cout << endl;
}
```

24.12 Enum classes

The C-style `enum` keyword introduced global names, so

```cpp
enum colors { red, yellow, green };
cout << red << "," << yellow << "," << green << endl;
```

do not work.

In C++ the `enum class` (or `enum struct`) was introduced, which makes the names into class members:

```cpp
enum class colors { red, yellow, green };
cout << static_cast<int>( colors::red ) << "," << static_cast<int>( colors::yellow ) << "," << static_cast<int>( colors::green ) << endl;
```

Even if such a class inherits from an integral type, you still need to cast it occasionally:

```cpp
enum class flag : unsigned int { red, white, blue };
// but we still need to cast them
cout << static_cast<int>( flag::red ) << "," << static_cast<int>( flag::white ) << "," << static_cast<int>( flag::blue ) << endl;
```
Chapter 25

Concurrency

Concurrency is a difficult subject. For a good introduction watch https://www.youtube.com/watch?v=F6Ipn7gC0sY from which a lot of this is taken.

25.1 Thread creation

Use header

```
#include <thread>
```

A thread is an object of class `std::thread`, and creating it you immediately begin its execution. The thread constructor takes at least one argument, a `callable` (a function pointer or a lambda), and optionally the arguments of that function-like object.

The environment that calls the thread needs to call `join` to ensure the completion of the thread.

```cpp
auto start_time = Clock::now();
auto waiting_thread = 
    std::thread( () { 
    sleep(1);
    } );
waiting_thread.join();
auto duration = Clock::now() - start_time;
```

Output

[thread] block:

This took 1.00522 sec

25.2 Synchronization

Threads run concurrent with the environment (or thread) that created them. That means that there is no temporal ordering between actions prior to synchronization with `std::thread::join`.

In this example, the concurrent updates of `counter` form a `data race`:
Formally, this program has Undefined Behavior (UB), which you see reflected in the different final values.

The final value can be fixed by declaring the counter as `std::atomic`:

```
auto start_time = myclock::now();
auto deadline = myclock::now() + std::chrono::seconds(1);
std::atomic<int> counter(0);
auto add_thread = 
    std::thread( [&counter, deadline] () {
        while (myclock::now()<deadline)
            printf("Thread: %d\n", ++counter);
    });
while (myclock::now()<deadline)
    printf("Main: %d\n", ++counter);
add_thread.join();
cout << "Final value: " << counter << endl;
```

Note that the accesses by the main and the thread are still not predictable, but that is a feature, not a bug, and definitely not UB
Chapter 26

Obscure stuff

26.1 Auto

This is not actually obscure, but it intersects many other topics, so we put it here for now.

26.1.1 Declarations

Sometimes the type of a variable is obvious:

```cpp
std::vector<std::shared_ptr<myclass>>*
myvar = new std::vector<std::shared_ptr<myclass>>
    (20, new myclass(1.3));
```

(Pointer to vector of 20 shared pointers to myclass, initialized with unique instances.) You can write this as:

```cpp
auto myvar = new std::vector<std::shared_ptr<myclass>>
    (20, new myclass(1.3));
```

Type deduction in functions

Return type can be deduced in C++17:

```cpp
auto equal(int i, int j) {
    return i==j;
};
```

Type deduction in methods

Return type of methods can be deduced in C++17:

```cpp
class A {
    private: float data;
    public:
        A(float i) : data(i) {};
        auto &access() {
            return data;
        }
        void print() {
            cout << "data: " << data << endl;
        }
};
```
26. Obscure stuff

Auto and references, 1

Auto discards references and such:

**Code:**
```
A my_a(5.7);
auto get_data = my_a.access();
get_data += 1;
my_a.print();
```

**Output**

[auto] plainget:
```
data: 5.7
```

Auto and references, 2

Combine auto and references:

**Code:**
```
A my_a(5.7);
auto &get_data = my_a.access();
get_data += 1;
my_a.print();
```

**Output**

[auto] refget:
```
data: 6.7
```

Auto and references, 3

For good measure:

```
A my_a(5.7);
const auto &get_data = my_a.access();
get_data += 1; // WRONG does not compile
my_a.print();
```

26.1.2 Iterating

Auto iterators

```
vector<int> myvector(20);
for ( auto copy_of_int : myvector )
    s += copy_of_int;
for ( auto &ref_to_int : myvector )
    ref_to_int = s;
for ( const auto &copy_of_thing : myvector )
    s += copy_of_thing.f();
```

is actually short for:

```
for ( std::vector<int> iterator it=myvector.begin();
    it!=myvector.end(); ++it )
    s += *it; // note the deref
```

Range iterators can be used with anything that is iterable
(vector, map, your own classes!)

Other iterator uses

Reverse iteration can not be done with range-based syntax.

Use general syntax with reverse iterator: rbegin, rend.

Iterator arithmetic

```
auto first = myarray.begin();
first += 2;
```
26.2. Iterating over classes

```cpp
auto last = myarray.end();
last -= 2;
myarray.erase(first, last);
```

26.1.3 decltype: declared type

There are places where you want the compiler to deduce the type of a variable, but where this is not immediately possible. Suppose that in

```cpp
auto v = some_object.get_stuff();
f(v);
```

you want to put a `try ... catch` block around just the creation of `v`. This does not work:

```cpp
try {
    auto v = some_object.get_stuff();
} catch (...) {}
f(v);
```

because the `try` block is a scope. It also doesn’t work to write

```cpp
auto v;
try {
    v = some_object.get_stuff();
} catch (...) {}
f(v);
```

because there is no indication what type `v` is created with.

Instead, it is possible to query the type of the expression that creates `v` with `decltype`:

```cpp
decltype(some_object.get_stuff()) v;
try {
    auto v = some_objects.get_stuff();
} catch (...) {}
f(v);
```

11.8.3

26.2 Iterating over classes

You know that you can iterate over `vector` objects:

```cpp
vector<int> myvector(20);
for (auto copy_of_int : myvector )
    s += copy_of_int;
for (auto &ref_to_int : myvector )
    ref_to_int = s;
```

(Many other STL classes are iterable like this.)

This is not magic: it is possible to iterate over any class: a `class` is `iteratable` that has a number of conditions satisfied.

The class needs to have:
• a method `begin` with prototype

```cpp
iteratableClass::begin()
```
That gives an object in the initial state, which we will call the ‘iterator object’; likewise
• a method `end`

```cpp
iteratableClass::end()
```
that gives an object in the final state; furthermore you need
• an increment operator

```cpp
void iteratorClass::operator++()
```
that advances the iterator object to the next state;
• a test

```cpp
bool iteratorClass::operator!=(const iteratorClass&)
```
to determine whether the iteration can continue; finally
• a dereference operator

```cpp
iteratorClass::operator*()
```
that takes the iterator object and returns its state.

### Simple illustration

Let’s make a class, called a `bag`, that models a set of integers, and we want to enumerate them. For simplicity sake we will make a set of contiguous integers:

```cpp
class bag {
    // basic data
    private:
        int first, last;
    public:
        bag(int first, int last) : first(first), last(last) {};
}
```

### Internal state

When you create an iterator object it will be copy of the object you are iterating over, except that it remembers how far it has searched:

```cpp
private:
    int seek{0};
```

### Initial/final state

The `begin` method gives a `bag` with the `seek` parameter initialized:

```cpp
public:
    bag &begin() { seek = first; return *this; };
    bag end() { seek = last; return *this; };
```

These routines are public because they are (implicitly) called by the client code.
26.2. Iterating over classes

Termination test

The termination test method is called on the iterator, comparing it to the `end` object:

```cpp
bool operator!=(const bag &test) const {
    return seek<=test.last;
}
```

Dereference

Finally, we need the increment method and the dereference. Both access the `seek` member:

```cpp
void operator++() { seek++; }
int operator*() { return seek; }
```

Use case

We can iterate over our own class:

```cpp
bag digits(0,9);
bool find3{false};
for ( auto seek : digits )
    find3 = find3 || (seek==3);
cout << "found 3: " << boolalpha << find3 << endl;

bool find15{false};
for ( auto seek : digits )
    find15 = find15 || (seek==15);
cout << "found 15: " << boolalpha << find15 << endl;
```

(For this particular case, use `std::any_of`)

With algorithms

```cpp
bool find8 = any_of(digits.begin(),digits.end(),
    [=] (int i) { return i==8; } );
cout << "found 8: " << boolalpha << find8 << endl;
```

If we add a method `has` to the class:

```cpp
bool has(int tst) {
    for (auto seek : *this )
        if (seek==tst) return true;
    return false;
}
```

we can call this:

```cpp
cout << "f3: " << digits.has(3) << endl;
cout << "f15: " << digits.has(15) << endl;
```
Of course, we could have written this function without the range-based iteration, but this implementation is particularly elegant.

**Exercise 26.1.** You can now do exercise 52.20, implementing a prime number generator with this mechanism.

If you think you understand `const`, consider that the `has` method is conceptually `cost`. But if you add that keyword, the compiler will complain about that use of `*this`, since it is altered through the `begin` method.

**Exercise 26.2.** Find a way to make `has` `const` method.

### 26.3 Casts

In C++, constants and variables have clear types. For cases where you want to force the type to be something else, there is the `cast` mechanism. With a cast you tell the compiler: treat this thing as such-and-such a type, no matter how it was defined.

In C, there was only one casting mechanism:

```c
sometype x;
othertype y = (othertype)x;
```

This mechanism is still available as the `reinterpret_cast`, which does 'take this byte and pretend it is the following type':

```c
sometype x;
auto y = reinterpret_cast<othertype>(x);
```

The inheritance mechanism necessitates another casting mechanism. An object from a derived class contains in it all the information of the base class. It is easy enough to take a pointer to the derived class, the bigger object, and cast it to a pointer to the base object. The other way is harder.

Consider:

```c
class Base {};
class Derived : public Base {};
Base *dobject = new Derived;
```

Can we now cast `dobject` to a pointer-to-derived?

- `static_cast` assumes that you know what you are doing, and it moves the pointer regardless.
- `dynamic_cast` checks whether `dobject` was actually of class `Derived` before it moves the pointer, and returns `nullptr` otherwise.

**Remark 14** One further problem with the C-style casts is that their syntax is hard to spot, for instance by searching in an editor. Because C++ casts have a unique keyword, they are easier to recognize in a text editor.
26.3. Casts

26.3.1 Static cast

One use of casting is to convert to constants to a ‘larger’ type. For instance, allocation does not use integers but `size_t`.

```c++
int hundredk = 100000;
int overflow;
overflow = hundredk * hundredk;
cout << "overflow: " << overflow << endl;
size_t bignumber = static_cast<size_t>(hundredk) * hundredk;
cout << "bignumber: " << bignumber << endl;
```

However, if the conversion is possible, the result may still not be ‘correct’.

```c++
long int hundredg = 100000000000;
cout << "long number: " << hundredg << endl;
int overflow;
overflow = static_cast<int>(hundredg);
cout << "assigned to int: " << overflow << endl;
```

There are no runtime tests on static casting.

Static casts are a good way of casting back void pointers to what they were originally.

26.3.2 Dynamic cast

Consider the case where we have a base class and derived classes.

```c++
class Base {
    public:
        virtual void print() = 0;
};
class Derived : public Base {
    public:
        virtual void print() {
            cout << "Construct derived!" << endl;
        }
};
class Erived : public Base {
    public:
        virtual void print() {
            cout << "Construct erived!" << endl;
        }
};
```

Also suppose that we have a function that takes a pointer to the base class: missing snippet polymain

The function can discover what derived class the base pointer refers to:
If we have a pointer to a derived object, stored in a pointer to a base class object, it’s possible to turn it safely into a derived pointer again:

**Code:**

```cpp
void f( Base *obj ) {
    Derived *der =
        dynamic_cast<Derived*>(obj);
    if (der==nullptr)
        cout << "Could not be cast to Derived"
            << endl;
    else
        der->print();
};
/* ... */
Base *object = new Derived();
f(object);
Base *nobject = new Erived();
f(nobject);
```

**Output**

[cast] deriveright:

On the other hand, a **static_cast** would not do the job:

**Code:**

```cpp
void g( Base *obj ) {
    Derived *der =
        static_cast<Derived*>(obj);
    der->print();
};
/* ... */
Base *object = new Derived();
g(object);
Base *nobject = new Erived();
g(nobject);
```

**Output**

[cast] derivewrong:

Note: the base class needs to be polymorphic, meaning that that pure virtual method is needed. This is not the case with a static cast, but, as said, this does not work correctly in this case.
26.3.3 Const cast

With \texttt{const\_cast} you can add or remove const from a variable. This is the only cast that can do this.

26.3.4 Reinterpret cast

The \texttt{reinterpret\_cast} is the crudest cast, and it corresponds to the C mechanism of ‘take this byte and pretend it of type whatever’. There is a legitimate use for this:

\begin{verbatim}
void *ptr;
ptr = malloc( how\_much );
auto address = reinterpret\_cast<long int>(ptr);
\end{verbatim}

so that you can do arithmetic on the address. For this particular case, \texttt{intptr\_t} is actually better.

26.3.5 A word about void pointers

A traditional use for casts in C was the treatment of \textit{void pointers}. The need for this is not as severe in C++ as it was before.

A typical use of void pointers appears in the PETSc [3, 4] library. Normally when you call a library routine, you have no further access to what happens inside that routine. However, PETSc has the functionality for you to specify a monitor so that you can print out internal quantities.

\begin{verbatim}
int KSPSetMonitor(KSP ksp,
int (*monitor)(KSP,int,PetscReal,\texttt{void*}),
\texttt{void} *context,
// one parameter omitted
);
\end{verbatim}

Here you can declare your own monitor routine that will be called internally: the library makes a \textit{callback} to your code. Since the library can not predict whether your monitor routine may need further information in order to function, there is the \texttt{context} argument, where you can pass a structure as void pointer.

This mechanism is no longer needed in C++ where you would use a \textit{lambda} (section 7.6):

\begin{verbatim}
KSPSetMonitor( ksp,
[mycontext] (KSP k,\texttt{int },PetscReal r) \rightarrow \texttt{int} { my_monitor_function(k,r,mycontext); } );
\end{verbatim}

26.4 Ivalue vs rvalue

The terms ‘lvalue’ and ‘rvalue’ sometimes appear in compiler error messages.

\begin{verbatim}
int foo() {return 2;}

int main()
{
    foo() = 2;

    return 0;
\end{verbatim}
26. Obscure stuff

See the ‘lvalue’ and ‘left operand’? To first order of approximation you’re forgiven for thinking that an lvalue is something on the left side of an assignment. The name actually means ‘locator value’: something that’s associated with a specific location in memory. Thus an lvalue is, also loosely, something that can be modified.

An rvalue is then something that appears on the right side of an assignment, but is really defined as everything that’s not an lvalue. Typically, rvalues can not be modified.

The assignment \( x = 1 \) is legal because a variable \( x \) is at some specific location in memory, so it can be assigned to. On the other hand, \( x + 1 = 1 \) is not legal, since \( x + 1 \) is at best a temporary, therefore not at a specific memory location, and thus not an lvalue.

Less trivial examples:

```c
int foo() { x = 1; return x; }
int main() {
    foo() = 2;
}
```

is not legal because \( \text{foo} \) does not return an lvalue. However,

```c
class foo {
private:
    int x;
public:
    int &xfoo() { return x; };
    int main() {
        foo x;
        x.xfoo() = 2;
    }
}
```

is legal because the function \( \text{xfoo} \) returns a reference to the non-temporary variable \( x \) of the \( \text{foo} \) object.

Not every lvalue can be assigned to: in

```c
const int a = 2;
```

the variable \( a \) is an lvalue, but can not appear on the left hand side of an assignment.

26.4.1 Conversion

Most lvalues can quickly be converted to rvalues:

```c
int a = 1;
int b = a+1;
```

Here \( a \) first functions as lvalue, but becomes an rvalue in the second line.

The ampersand operator takes an lvalue and gives an rvalue:
```cpp
int i;
int *a = &i;
*i = 5; // wrong
```

### 26.4.2 References

The ampersand operator yields a reference. It needs to be assigned from an lvalue, so

```cpp
std::string &s = std::string(); // wrong
```

is illegal. The type of `s` is an ‘lvalue reference’ and it can not be assigned from an rvalue.

On the other hand

```cpp
const std::string &s = std::string();
```

works, since `s` can not be modified any further.

### 26.4.3 Rvalue references

A new feature of C++ is intended to minimize the amount of data copying through *move semantics*.

Consider a copy assignment operator

```cpp
BigThings& operator=( const BigThing &other ) {
    BigThing tmp(other); // standard copy
    std::swap( /* tmp data into my data */ );
    return *this;
};
```

This calls a copy constructor and a destructor on `tmp`. (The use of a temporary makes this safe under exceptions. The `swap` method never throws an exception, so there is no danger of half-copied memory.)

However, if you assign

```cpp
thing = BigThing(stuff);
```

Now a constructor and destructor is called for the temporary rvalue object on the right-hand side.

Using a syntax that is new in C++, we create an *rvalue reference*:

```cpp
BigThings& operator=( BigThing &&other ) {
    swap( /* other into me */ );
    return *this;
}
```

### 26.5 Move semantics

With an *overloaded operator*, such as addition, on matrices (or any other big object):

```cpp
Matrix operator+(Matrix &a, Matrix &b);
```

the actual addition will involve a copy:
26. Obscure stuff

\[ \text{Matrix } c = a \ast b; \]

Use a move constructor:

```cpp
class Matrix {
    private:
        Representation rep;
    public:
        Matrix(Matrix &&a) {
            rep = a.rep;
            a.rep = {};
        }
};
```

26.6 Graphics

C++ has no built-in graphics facilities, so you have to use external libraries such as OpenFrameworks, [https://openframeworks.cc](https://openframeworks.cc).

26.7 Standards timeline

Each standard has many changes over the previous.

If you want to detect what language standard you are compiling with, use the \_\_cpluscplus macro:

```cpp
Code:
    cout << "C++ version: " << \_\_cpluscplus << endl;
Output
[basic] version:
    C++ version: 201703
```

This returns a long int with possible values 199711, 201103, 201402, 201703, 202002.

Here are some of the highlights of the various standards.

26.7.1 C++98/C++03

Of the C++03 standard we only highlight deprecated features.

- `auto_ptr` was an early attempt at smart pointers. It is deprecated, and C++17 compilers will actually issue an error on it. For current smart pointers see chapter 16.

26.7.2 C++11

- `auto`

```cpp
    const auto count = std::count
                        (begin(vec), end(vec), value);
```

The `count` variable now gets the type of whatever `vec` contained.

- Range-based for. We have been treating this as the base case, for instance in section 11.2. The C++11 mechanism, using an iterator (section 24.2.2) is largely obviated.
26.7. Standards timeline

• Lambdas. See section 7.6.
• Variadic templates.
• Unique pointer.

    unique_ptr<int> iptr( new int(5) );

This fixes problems with auto_ptr.
• constexpr

    constexpr int get_value() {
        return 5*3;
    }

26.7.3 C++14

C++14 can be considered a bug fix on C++11. It simplifies a number of things and makes them more
elegant.
• Auto return type deduction:

    auto f() {
        SomeType something;
        return something;
    }

• Generic lambdas (section 7.6.4)

    const auto count = std::count(begin(vec),end(vec),
        [] ( const auto i ) { return i<3; })
    );

Also more sophisticated capture expressions.
• Unique pointer

    auto iptr( make_unique<int>(5) );

This makes new and delete completely superfluous.
• constexpr

    constexpr int get_value() {
        int val = 5;
        int val2 = 3;
        return val*val2
    }

26.7.4 C++17

• Optional; section 24.5.2.
• Structured binding declarations as an easier way of dissecting tuples; section 24.4.
• Init statement in conditionals; section ??.

26.7.5 C++20

• modules: these offer a better interface specification than using header files.
• coroutines, another form of parallelism.
• concepts including in the standard library via ranges; section 22.4.
26. Obscure stuff

- *spaceship operator* including in the standard library
- broad use of normal C++ for direct compile-time programming, without resorting to template metaprogramming (see last trip reports)
- *ranges*
- *calendars and time zones*
- *text formatting*
- *span*. See section 11.8.5.
- *numbers*. Section 24.7.

Here is a summary with examples: https://oleksandrkvl.github.io/2021/04/02/cpp-20-overview.html.
Chapter 27

Graphics

The C++ language and standard library do not have graphics components. However, the following projects exist.

https://www.sfml-dev.org/
Chapter 28

C++ for C programmers

28.1 I/O

There is little employ for `printf` and `scanf`. Use `cout` (and `cerr`) and `cin` instead. There is also the `fmtlib` library.

Chapter 13.

28.2 Arrays

Arrays through square bracket notation are unsafe. They are basically a pointer, which means they carry no information beyond the memory location.

It is much better to use `vector`. Use range-based loops, even if you use bracket notation.

Chapter 11.

Vectors own their data exclusively, so having multiple C style pointers into the same data act like so many arrays does not work. For that, use the `span`; section 11.8.5.

28.2.1 Vectors from C arrays

Suppose you have to interface to a C code that uses `malloc`. Vectors have advantages, such as that they know their size, you may want to wrap these C style arrays in a vector object. This can be done using a range constructor:

```cpp
vector<double> x( pointer_to_first, pointer_after_last );
```

Such vectors can still be used dynamically, but this may give a memory leak and other possibly unwanted behavior:
28. C++ for C programmers

```c
float *x;
x = (float*)malloc(length*sizeof(float));
/* ... */
vector<float> xvector(x, x+length);
cout << "xvector has size: " << xvector.size();
cout << "Push back was successful" << endl;
cout << "pushed element: " << xvector.at(length) << endl;
cout << "original array: "
     << x[length] << endl;
```

Output

```
array: cvector:
xvector has size: 53
Push back was successful
pushed element: 5
original array: 0
```

### 28.3 Dynamic storage

Another advantage of vectors and other containers is the **RAII** mechanism, which implies that dynamic storage automatically gets deallocated when leaving a scope. Section 11.8.3. (For safe dynamic storage that transcends scope, see smart pointers discussed below.)

RAII stands for ‘Resource Allocation Is Initialization’. This means that it is no longer possible to write

```c
double *x;
if (something1) x = malloc(10);
if (something2) x[0];
```

which may give a memory error. Instead, declaration of the name and allocation of the storage are one indivisible action.

On the other hand:

```c
vector<double> x(10);
```

declares the variable `x`, allocates the dynamic storage, and initializes it.

### 28.4 Strings

A *C string* is a character array with a **null terminator**. On the other hand, a *string* is an object with operations defined on it.

Chapter 12.

### 28.5 Pointers

Many of the uses for *C pointers*, which are really addresses, have gone away.

- Strings are done through `std::string`, not character arrays; see above.
• Arrays can largely be done through `std::vector`, rather than `malloc`; see above.
• Traversing arrays and vectors can be done with ranges; section 11.2.
• To pass an argument by reference, use a reference. Section 7.4.
• Anything that obeys a scope should be created through a constructor, rather than using `malloc`.

There are some legitimate needs for pointers, such as Objects on the heap. In that case, use `shared_ptr` or `unique_ptr`; section 16.2. The C pointers are now called bare pointers, and they can still be used for ‘non-owning’ occurrences of pointers.

28.5.1 Parameter passing

No longer by address: now true references! Section 7.4.

28.6 Objects

Objects are structures with functions attached to them. Chapter 10.

28.7 Namespaces

No longer name conflicts from loading two packages: each can have its own namespace. Chapter 20.

28.8 Templates

If you find yourself writing the same function for a number of types, you’ll love templates. Chapter 22.

28.9 Obscure stuff

28.9.1 Lambda

Function expressions. Section 7.6.

28.9.2 Const

Functions and arguments can be declared const. This helps the compiler. Section 18.1.

28.9.3 Lvalue and rvalue

Section 26.4.
28. C++ for C programmers
Chapter 29

C++ review questions

29.1 Arithmetic
1. Given
   ```cpp
   int n;
   ```
   write code that uses elementary mathematical operators to compute $n$-cubed: $n^3$.
   Do you get the correct result for all $n$? Explain.
2. What is the output of:
   ```cpp
   int m=32, n=17;
   cout << n%m << endl;
   ```

29.2 Looping
1. Suppose a function
   ```cpp
   bool f(int);
   ```
   is given, which is true for some positive input value. Write a main program that finds the
   smallest positive input value for which $f$ is true.
2. Suppose a function
   ```cpp
   bool f(int);
   ```
   is given, which is true for some negative input value. Write a main program that finds the
   (negative) input with smallest absolute value for which $f$ is true.

29.3 Functions

Exercise 29.1. The following code snippet computes in a loop the recurrence
   $$v_{i+1} = av_i + b, \quad v_0 \text{ given.}$$
Write a recursive function
29. C++ review questions

\[ \text{float } v = \text{value}_n(n, a, b, v_0); \]

that computes the value \( v_n \) for \( n \geq 0 \).

29.4 Vectors

Exercise 29.2. The following program has several syntax and logical errors. The intended purpose is to read an integer \( N \), and sort the integers \( 1, \ldots, N \) into two vectors, one for the odds and one for the evens. The odds should then be multiplied by two.

Your assignment is to debug this program. For 10 points of credit, find 10 errors and correct them. Extra errors found will count as bonus points. For logic errors, that is, places that are syntactically correct, but still ‘do the wrong thing’, indicate in a few words the problem with the program logic.

```cpp
#include <iostream>
using std::cout; using std::cin;
using std::vector;

int main() {
    vector<int> evens, odds;
    cout << "Enter an integer value " << endl;
    cin << N;
    for (i=0; i<N; i++) {
        if (i%2==0) {
            odds.push_back(i);
        } else
            evens.push_back(i);
    }
    for (auto o : odds )
        o *= 2
    return 1
}
```

29.5 Vectors

Exercise 29.3. Take another look at exercise 29.1. Now assume that you want to save the values \( v_i \) in an array `vector<float> values`. Write code that does that, using first the iterative, then the recursive computation. Which do you prefer?

29.6 Objects
Exercise 29.4. Let a class `Point` class be given. How would you design a class `SetOfPoints` (which models a set of points) so that you could write

```cpp
Point p1, p2, p3;
SetOfPoints pointset;
// add points to the set:
pointset.add(p1); pointset.add(p2);
```

Give the relevant data members and methods of the class.

Exercise 29.5. You are programming a video game. There are moving elements, and you want to have an object for each. Moving elements need to have a method `move` with an argument that indicates a time duration, and this method updates the position of the element, using the speed of that object and the duration.

Supply the missing bits of code.

```cpp
class position {
    /* ... */
public:
    position() {};
    position(int initial) { /* ... */ };
    void move(int distance) { /* ... */ };
};
class actor {
protected:
    int speed;
    position current;

public:
    actor() { current = position(0); }
    void move(int duration) {
        /* THIS IS THE EXERCISE: */
        /* write the body of this function */
    }
};
class human : public actor {
public:
    human() // EXERCISE: write the constructor
};
class airplane : public actor {
public:
    airplane() // EXERCISE: write the constructor
};

int main() {
    human Alice;
```
airplane Seven47;
Alice.move( 5 );
Seven47.move( 5 );
PART III

FORTRAN
Chapter 30

Basics of Fortran

Fortran is an old programming language, dating back to the 1950s, and the first ‘high level programming language’ that was widely used. In a way, the fields of programming language design and compiler writing started with Fortran, rather than this language being based on established fields. Thus, the design of Fortran has some idiosyncracies that later designed languages have not adopted. Many of these are now ‘deprecated’ or simply inadvisable. Fortunately, it is possible to write Fortran in a way that is every bit as modern and sophisticated as other current languages.

In this part of our book, we will teach you safe practices for writing Fortran. Occasionally we will not mention practices that you will come across in old Fortran codes, but that we would not advise you taking up. While our exposition of Fortran can stand on its own, we will in places point out explicitly differences with C++.

For secondary reading, this is a good course on modern Fortran: http://www.pcc.qub.ac.uk/tec/courses/f77tof90/stu-notes/f90studentMIF_1.html

30.1 Source format

Fortran started in the era when programs were stored on punch cards. Those had 80 columns, so a line of Fortran source code could not have more than 80 characters. Also, the first 6 characters had special meaning. This is referred to as fixed format. However, starting with Fortran 90 it became possible to have free format, which allowed longer lines without special meaning for the initial columns.

There are further differences between the two formats (notably continuation lines) but we will only discuss free format in this course.

Many compilers have a convention for indicating the source format by the file name extension:

- f and F are the extensions for old-style fixed format; and
- f90 and F90 are the extensions for new free format.

Capital letters indicate that the C preprocessor is applied to the file. For this course we will use the F90 extension.
30. Basics of Fortran

30.2 Compiling Fortran

For Fortran programs, the compiler is `gfortran` for the GNU compiler, and `ifort` for Intel.

The minimal Fortran program is:

```fortran
Program SomeProgram
  ! stuff goes here
End Program SomeProgram
```

Exercise 30.1. Add the line
```
print *, "Hello world!"
```
to the empty program, and compile and run it.

Fortran ignores case. Keywords such as `Program` can just as well be written as `PrOgRaM`.

A program optionally has a `stop` statement, which can return a message to the OS.

<table>
<thead>
<tr>
<th>Code:</th>
</tr>
</thead>
</table>
| Program SomeProgram  
  stop 'the code stops here'  
End Program SomeProgram |
| Output |
| [basicf] stop:  
STOP the code stops here |

30.3 Main program

Fortran does not use curly brackets to delineate blocks, instead you will find `end` statements. The very first one appears right when you start writing your program: a Fortran program needs to start with a `Program` line, and end with `End Program`. The program needs to have a name on both lines:

```fortran
Program SomeProgram  
  ! stuff goes here  
End Program SomeProgram
```

and you can not use that name for any entities in the program.

Remark 15 The emacs editor will supply the block type and name if you supply the ‘end’ and hit the TAB or RETURN key; see section 2.1.1.

30.3.1 Program structure

Unlike C++, Fortran can not mix variable declarations and executable statements, so both the main program and any subprograms have roughly a structure:

```fortran
Program foo  
  < declarations >  
  < statements >  
End Program foo
```

Another thing to note is that there are no include directives. Fortran does not have a ‘standard library’ such as C++ that needs to be explicitly included.
30.3.2 Statements

Let’s say a word about layout. Fortran has a ‘one line, one statement’ principle.

- As long as a statement fits on one line, you don’t have to terminate it explicitly with something like a semicolon:

  \[
  x = 1 \\
  y = 2
  \]

- If you want to put two statements on one line, you have to terminate the first one:

  \[
  x = 1; \\
  y = 2
  \]

But watch out for the line length: this is often limited to 132 characters.

- If a statement spans more than one line, all but the first line need to have an explicit continuation character, the ampersand:

  \[
  x = \text{very } \& \\
  \text{long } \& \\
  \text{expression}
  \]

30.3.3 Comments

Fortran knows only single-line comments, indicated by an exclamation point:

\[
\text{x = 1 ! set x to one}
\]

Everything from the exclamation point onwards is ignored.

Maybe not entirely obvious: you can have a comment after a continuation character:

\[
\text{x = f(a) } \& \\
\text{+ g(b) } \&
\]

30.4 Variables

Unlike in C++, where you can declare a variable right before you need it, Fortran wants its variables declared near the top of the program or subprogram:

\[
\text{Program YourProgram} \\
\text{implicit none} \\
\text{! variable declaration} \\
\text{! executable code}
\]

\[
\text{End Program YourProgram}
\]

A variable declaration looks like:

\[
\text{type [ , attributes ] :: name1 [ , name2, .... ]}
\]

where

- we use the common grammar shorthand that \[ \text{something} \] stands for an optional ‘something’;
- \text{type} is most commonly \text{integer, real(4), real(8), logical}. See below; section 30.4.1.

Victor Eijkhout 285
• the optional attributes are things such as dimension, allocatable, intent, parameter et cetera.
• name is something you come up with. This has to start with a letter.

The built-in data types of Fortran:

```
Data types
• Numeric: Integer, Real, Complex (section 30.6).
• Logical: Logical.
• Character: Character. Strings are realized as arrays of characters.
```

Some variables are not intended every to change, such as if you introduce a variable \( \pi \) with value 3.14159. You can mark this name being a synonym for the value, rather than a variable you can assign to, with the parameter keyword.

```
real, parameter :: \( \pi \) = 3.141592
```

In chapter 39 you will see that parameters are often used for defining the size of an array.

Further specifications for numerical precision are discussed in section 30.4.2. Strings are discussed in chapter 35.

### 30.4.1 Declarations

Fortran has a somewhat unusual treatment of variable types: if you don’t specify what data type a variable is, Fortran will deduce it from a simple rule, based on the first character of the name. This is a very dangerous practice, so we advocate putting a line

```
implicit none
```

immediately after any program or subprogram header. Now every variable needs to be given a type explicitly in a declaration.

You can the number of bytes for numerical types in the declaration:

```
integer(2) :: i2
integer(4) :: i4
integer(8) :: i8
real(4) :: r4
real(8) :: r8
real(16) :: r16
complex(8) :: c8
complex(16) :: c16
complex*32 :: c32
```

### 30.4.2 Precision

In Fortran you can actually ask for a type with specified precision.

• For integers you can specify the number of decimal digits with `selected_int_kind(n)`.
• For floating point numbers can specify the number of significant digits, and optionally the decimal exponent range with `selected_real_kind(p[,r])` of significant digits.
30.4. Variables

- To query the type of a variable, use the function `kind`, which returns an integer.

Likewise, you can specify the precision of a constant. Writing 3.14 will usually be a single precision real.

**Single/double precision constants**

<table>
<thead>
<tr>
<th>Code:</th>
<th>Output [basic] e0:</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>real(8) :: x, y, z</code></td>
<td><code>1.1000000014901161</code></td>
</tr>
<tr>
<td><code>x = 1.</code></td>
<td><code>1.1000000000000001</code></td>
</tr>
<tr>
<td><code>y = .1</code></td>
<td></td>
</tr>
<tr>
<td><code>z = x + y</code></td>
<td></td>
</tr>
<tr>
<td><code>print *, z</code></td>
<td></td>
</tr>
<tr>
<td><code>x = 1.d0</code></td>
<td></td>
</tr>
<tr>
<td><code>y = .1d0</code></td>
<td></td>
</tr>
<tr>
<td><code>z = x + y</code></td>
<td></td>
</tr>
<tr>
<td><code>print *, z</code></td>
<td></td>
</tr>
</tbody>
</table>

You can query how many bytes a data type takes with `kind`.

**Numerical precision**

Number of bytes determines numerical precision:

- Computations in 4-byte have relative error $\approx 10^{-6}$
- Computations in 8-byte have relative error $\approx 10^{-15}$

Also different exponent range: max $10^{\pm 50}$ and $10^{\pm 300}$ respectively.

**Storage size**

F08: `storage_size` reports number of bits.

F95: `bit_size` works on integers only.

`c_sizeof` reports number of bytes, requires `iso_c_binding` module.

Force a constant to be `real(8)`:

**Double precision constants**

<table>
<thead>
<tr>
<th><code>real(8) :: x, y</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>x = 3.14d0</code></td>
</tr>
<tr>
<td><code>y = 6.022e-23</code></td>
</tr>
</tbody>
</table>

- Use a compiler flag such as `-r8` to force all reals to be 8-byte.
- Write `3.14d0`
- `x = real(3.14, kind=8)`

### 30.4.3 Initialization

Variables can be initialized in their declaration:

<table>
<thead>
<tr>
<th><code>integer :: i=2</code></th>
</tr>
</thead>
<tbody>
<tr>
<td><code>real(4) :: x = 1.5</code></td>
</tr>
</tbody>
</table>

That this is done at compile time, leading to a common error:

Victor Eijkhout
subroutine foo()
  implicit none
  integer :: i=2
  print *, i
  i = 3
end subroutine foo

On the first subroutine call $i$ is printed with its initialized value, but on the second call this initialization is not repeated, and the previous value of 3 is remembered.

### 30.5 Quick comparison Fortran vs C++

#### 30.5.1 Statements

**Fortran statements**

It’s all much like C++:

- **Assignments:**
  
  
  \[
  x = y \\
  x = 2*y / (a+b)
  \]

- **I/O:** next
- **conditionals and loops:** later
- **function calls:** later

#### 30.5.2 Input/Output, or I/O as we say

**Simple I/O**

- **Input:**
  
  \[
  \text{READ } *, n
  \]

- **Output:**
  
  \[
  \text{PRINT } *, n
  \]

There is also **Write**.

The ‘star’ indicates that default formatting is used.

Other syntax for read/write with files and formats.

#### 30.5.3 Expressions

**Arithmetic expressions**

- Pretty much as in C++
- Exception: $r^a$ for power $r^a$
- Modulus is a function: \texttt{MOD} (7, 3).

**Boolean expressions**

- Long form:
  
  .and. .not. .or.
  .lt. .le. .eq. .ne. .ge. .gt.
30.6 Complex numbers

A complex number is a pair of real numbers. Complex constants can be written with a parenthesis notation, but to form a complex number from two real variables requires the \texttt{CMPLX} function.

Real and imaginary parts can be extracted with the function \texttt{real} and \texttt{aimag}.

Complex constants are written as a pair of reals in parentheses. There are some basic operations.

\begin{verbatim}
Complex :: 
  fourtyfivedegrees = (1.,1.), &
  number,rotated
Real :: x,y
print *,"45 degrees:",fourtyfivedegrees
x = 3.; y = 1.; number = cmplx(x,y)
rotated = number * fourtyfivedegrees
print '("Rotated number has Re="',f5.2," Im="',f5.2,'"",&
  real(rotated),aimag(rotated)
\end{verbatim}

The imaginary root $i$ is not predefined. Use

\begin{verbatim}
Complex,parameter :: i = (0,1)
\end{verbatim}

In Fortran2008, \texttt{Complex} is a derived type, and the real/imaginary parts can be extracted as

\begin{verbatim}
print *,rotated%re,rotated%im
\end{verbatim}

http://userweb.eng.gla.ac.uk/peter.smart/com/com/f77-conv.htm
30. Basics of Fortran

**Code:**

```fortran
print *, "45 degrees:", fortyfivedegrees
x = 3.; y = 1.; number = cmplx(x,y)
rotated = number * fortyfivedegrees
print '("Rotated number has Re=",f5.2," Im=",',
       rotated%re,rotated%im
```

**Output**

```
[basicf] complexf08:
45 degrees: (1.00000000,1.00000000)
Rotated number has Re= 2.00 Im= 4.00
```

### 30.7 Review questions

**Exercise 30.2.** What is the output for this fragment, assuming \( i, j \) are integers?

```fortran
integer :: idiv
!! ...
  i = 3 ; j = 2 ; idiv = i/j
print *,idiv
```

**Exercise 30.3.** What is the output for this fragment, assuming \( i, j \) are integers?

```fortran
real :: fdiv
!! ...
  i = 3 ; j = 2 ; fdiv = i/j
print *,fdiv
```

**Exercise 30.4.** In declarations

```fortran
real(4) :: x
real(8) :: y
```

What do the 4 and 8 stand for?

What is the practical implication of using the one or the other?

**Exercise 30.5.** Write a program that:

- displays the message Type a number,
- accepts an integer number from you (use Read),
- makes another variable that is three times that integer plus one,
- and then prints out the second variable.
Exercise 30.6. In the following code, if value is nonzero, what do expect about the output?

```fortran
real(8) :: value8, should_be_value
real(4) :: value4
!! ...
print *,".. original value was:",value8
value4 = value8
print *,".. copied to single:",value4
should_be_value = value4
print *,".. copied back to double:",should_be_value
print *,"Difference:",value8-should_be_value
```
Chapter 31

Conditionals

31.1 Forms of the conditional statement

The Fortran conditional statement uses the if keyword:

**Conditionals**

Single line conditional:

\[
\text{if ( test ) statement}
\]

The full if-statement is:

\[
\begin{align*}
\text{if ( something ) then} \\
\text{!! something_doing} \\
\text{else} \\
\text{!! otherwise_else} \\
\text{end if}
\end{align*}
\]

The ‘else’ part is optional; you can nest conditionals.

You can label conditionals, which is good for readability but adds no functionality:

\[
\begin{align*}
\text{checkx: if ( ... some test on x ... ) then} \\
\text{checky: if ( ... some test on y ... ) then} \\
\text{!! code ...} \\
\text{end if checky} \\
\text{else checkx} \\
\text{!! code ...} \\
\text{end if checkx}
\end{align*}
\]

31.2 Operators

**Comparison and logical operators**
31. Conditionals

<table>
<thead>
<tr>
<th>Operator</th>
<th>old style</th>
<th>meaning</th>
<th>example</th>
</tr>
</thead>
<tbody>
<tr>
<td>==</td>
<td>.eq.</td>
<td>equals</td>
<td>x==y=1</td>
</tr>
<tr>
<td>/=</td>
<td>.ne.</td>
<td>not equals</td>
<td>x*x/=5</td>
</tr>
<tr>
<td>&gt;</td>
<td>.gt.</td>
<td>greater</td>
<td>y&gt;x=1</td>
</tr>
<tr>
<td>&gt;=</td>
<td>.ge.</td>
<td>greater or equal</td>
<td>sqrt(y)&gt;=7</td>
</tr>
<tr>
<td>&lt;</td>
<td>.lt.</td>
<td>less than</td>
<td></td>
</tr>
<tr>
<td>&lt;=</td>
<td>.le.</td>
<td>less or equal</td>
<td></td>
</tr>
<tr>
<td>.and.</td>
<td></td>
<td>and, or</td>
<td>x&lt;1 .and. x&gt;0</td>
</tr>
<tr>
<td>.or.</td>
<td></td>
<td>not</td>
<td></td>
</tr>
<tr>
<td>.equiv</td>
<td>.neqv.</td>
<td>equiv (iff, not XOR)</td>
<td></td>
</tr>
<tr>
<td>.true</td>
<td>.false</td>
<td>not equiv (XOR)</td>
<td></td>
</tr>
</tbody>
</table>

The logical operators such as .AND. are not short-cut as in C++. Clauses can be evaluated in any order.

Exercise 31.1. Read in three grades: Algebra, Biology, Chemistry, each on a scale 1···10. Compute the average grade, with the conditions:

- Algebra is always included.
- Biology is only included if it increases the average.
- Chemistry is only included if it is 6 or more.

31.3 Select statement

The Fortran equivalent of the C++ case statement is select. It takes single values or ranges; works for integers and characters.

Select statement

Test single values or ranges, integers or characters:

```
Select Case (i)
Case (:=-1)
  print *, "Negative"
Case (5)
  print *, "Five!"
Case (0)
  print *, "Zero."
Case (1:4, 6:!) ! can not have (1:)
  print *, "Positive"
end Select
```

Compiler does checking on overlapping cases!

Case values need to be constant expressions.

31.4 Boolean variables

The Fortran type for booleans is Logical.

The two literals are .true. and .false.
31.5. Review questions

Exercise 31.2. Print a boolean variable. What does the output look like in the true and false case?

31.5 Review questions

Exercise 31.3. What is a conceptual difference between the C++ switch and the Fortran Select statement?
31. Conditionals
Chapter 32

Loop constructs

32.1 Loop types

Fortran has the usual indexed and ‘while’ loops. There are variants of the basic loop, and both use the do keyword. The simplest loop has a loop variable, an upper bound, and a lower bound.

Indexed Do loops

```
integer :: i
do i=1,10
    ! code with i
end do
```

You can include a step size (which can be negative) as a third parameter:

```
do i=1,10,3
    ! code with i
end do
```

A couple of remarks about the loop variable:

- The loop variable is defined outside the loop, so it will have a value after the loop terminates.
- Non-integer loop variables are allowed, but be careful about the termination test. Because of floating point error you may run an iteration more or less than you were expecting.

Non-integer loop variables

Deleted language feature

Fraught with peril:
32. Loop constructs

**Code:**

```fortran
real(4) :: r
do r=.1,1.,.1
    print *,r
end do
```

**Output**

```
[loopf] loopr:
0.100000001
0.200000003
0.300000012
0.400000006
0.500000000
0.600000024
0.700000048
0.800000072
0.900000095
1.00000012
```

**Semantic fine points**

- Fortran loops determine the iteration count before execution; a loop will run that many iterations, unless you `Exit`.
- You are not allowed to alter the iteration variable.

**While loop**

The while loop has a pre-test:

```fortran
do while (i<1000)
    print *,i
    i = i*2
end do
```

You can label loops, which improves readability, but see also below.

```fortran
outer: do i=1,10
    inner: do j=1,10
        print *,j
    end do
end do outer
```

The label needs to be on the same line as the `do`, and if you use a label, you need to mention it on the `end do` line.

**Remark 16** There is a legacy mechanism of label-terminated loops. Please do not use them.

### 32.2 Interruptions of the control flow

For indeterminate looping, you can use the `while` test, or leave out the loop parameter altogether. In that case you need the `exit` statement to stop the iteration.

**Exit and cycle**

Loop without counter or while test:

```fortran
do
    call random_number(x)
    if (x>.9) exit
    print *,"Nine out of ten exes agree"
end do
```
Compare to \texttt{break} in C++.

Skip rest of current iteration:

\begin{verbatim}
do i=1,100  
   if (ispine(i)) cycle  
     ! do something with non-prime  
end do
\end{verbatim}

Compare to \texttt{continue} in C++.

Cycle and exit can apply to multiple levels, if the do-statements are labeled.

\begin{verbatim}
outer : do i = 1,10  
   inner : do j = 1,10  
      if (i+j>15) exit outer  
      if (i==j) cycle inner  
   end do inner  
end do outer
\end{verbatim}

### 32.3 Implied do-loops

There are do loops that you can write in a single line by an expression and a loop header. In effect, such an \textit{implied do loop} becomes the sum of the indexed expressions. This is useful for I/O. For instance, iterate a simple expression:

**Implied do loops**

Normally, each print statement is on a new line; use an implied loop to print on one line.

\begin{verbatim}
\textbf{Print }*, (2*i, i=1,20)
\end{verbatim}

You can iterate multiple expressions:

\begin{verbatim}
\textbf{Print }*, (2*i, 2*i+1, i=1,20)
\end{verbatim}

These loops can be nested:

\begin{verbatim}
\textbf{Print }*, ( i+j, i=1,20, j=1,20 )
\end{verbatim}

Also useful for \texttt{Read}.

This construct is especially useful for printing arrays.

**Exercise 32.1.** Use the implied do-loop mechanism to print a triangle:

\begin{verbatim}
1
2 2
3 3 3
4 4 4 4
\end{verbatim}

up to a number that is input.
32.4 Review questions

Exercise 32.2. What is the output of:

```plaintext
do i=1,11,3
   print *,i
end do
```

What is the output of:

```plaintext
do i=1,3,11
   print *,i
end do
```
Chapter 33

Scope

33.1 Scope

Fortran ‘has no curly brackets’: you not easily create nested scopes with local variables as in C++. For instance, the range between do and end do is not a scope. This means that all variables have to be declared at the top of a program or subprogram.

33.1.1 Variables local to a program unit

Variables declared in a subprogram have similar scope rules as in C++:

• Their visibility is controlled by their textual scope:

```fortran
Subroutine Foo()
    integer :: i
    ! ‘i’ can now be used
    call Bar()
    ! ‘i’ still exists
End Subroutine Foo

Subroutine Bar() ! no parameters
    ! The ‘i’ of Foo is unknown here
End Subroutine Bar
```

• Their dynamic scope is the lifetime of the program unit in which they are declared:

```fortran
Subroutine Foo()
    call Bar()
    call Bar()
End Subroutine Foo

Subroutine Bar()
    Integer :: i
    ! ‘i’ is created every time Bar is called
End Subroutine Bar
```

33.1.1.1 Variables in a module

Variables in a module (section 37.2) have a lifetime that is independent of the calling hierarchy of program units: they are static variables.
33. Scope

33.1.1.2 Other mechanisms for making static variables

Before Fortran gained the facility for recursive functions, the data of each function was placed in a
statically determined location. This meant that the second time you call a function, all variables still
have the value that they had last time. To force this behaviour in modern Fortran, you can add the `Save`
specification to a variable declaration.

Another mechanism for creating static data was the `Common` block. This should not be used, since a
`Module` is a more elegant solution to the same problem.

33.1.2 Variables in an internal procedure

An internal procedure (that is, one placed in the `Contains` part of a program unit) can receive arguments
from the containing program unit. It can also access directly any variable declared in the containing
program unit, through a process called host association.

The rules for this are messy, especially when considering implicit declaration of variables, so we advise
against relying on it.
Chapter 34

Procedures

Programs can have subprograms: parts of code that for some reason you want to separate from the main program. The term for these is *procedure*. This is a keyword, but you won’t see it used initially.

If you structure your code in a single file, this is the recommended structure:

**Procedures in contains clause**

```
Program foo
  < declarations>
  < executable statements >
  Contains
  < procedure definitions >
End Program foo
```

Two types of procedures: functions and subroutines. More later.

That is, procedures are placed after the main program statements, separated by a `Contains` clause.

In general, these are the placements of procedures:

- Internal: after the `Contains` clause of a program
- In a `Module`; see section 37.2.
- Externally: the procedure is not internal to a `Program` or `Module`. In this case it’s safest to declare it through an `Interface` specification; section 42.1.

### 34.1 Subroutines and functions

Fortran has two types of procedures:

- Subroutines, which are somewhat like *void* functions in C++: they can be used to structure the code, and they can only return information to the calling environment through their parameters.
- Functions, which are like C++ functions with a return value.

Both types have the same structure, which is roughly the same as of the main program:

```
subroutine foo( <parameters> )
  <variable declarations>
  <executable statements>
end subroutine foo
```

and
Exit from a procedure can happen two ways:
1. the flow of control reaches the end of the procedure body, or
2. execution is finished by an explicit `return` statement.

```
subroutine foo()
    print *,"foo"
    if (something) return
    print *,"bar"
end subroutine foo
```

The `return` statement is optional in the first case. The `return` statement is different from C++ in that it does not indicate the return result of a function.

**Exercise 34.1.** Rewrite the above subroutine `foo` without a `return` statement.

A subroutine is invoked with a `call` statement:
```
call foo()
```

### Subroutine with argument

**Code:**
```
program printing
  implicit none
  call printint(5)
contains
  subroutine printint(invalue)
    implicit none
    integer :: invalue
    print *,invalue
  end subroutine printint
end program printing
```

**Output**
```
[funcf] printone:
  5
```

### Subroutine can change argument

**Code:**
```
program printing
  implicit none
  call printint(invalue)
contains
  subroutine printint(invalue)
    implicit none
    integer :: invalue
    print *,invalue
  end subroutine printint
end program printing
```
34.2 Return results

While a subroutine can only return information through its parameters, a function procedure returns an explicit result:

```
logical function test(x)
  implicit none
  real :: x
  
test = some_test_on(x)
return ! optional, see above
end function test
```

You see that the result is not returned in the return statement, but rather through assignment to the function name. The return statement, as before, is optional and only indicates where the flow of control ends.
A function in Fortran is a procedure that return a result to its calling program, much like a non-void function in C++

**Function definition and usage**

- **subroutine** vs **function**: compare void functions vs non-void in C++.
- Return type, keyword **function**, name, parameters
- Function body has statements
- Result is returned by assigning to the function name
- Use: $y = f(x)$

**Function example**

```fortran
program plussing
    implicit none
    integer :: i
    i = plusone(5)
    print *,i
contains
    integer function plusone(invalue)
    implicit none
    integer :: invalue
    plusone = invalue+1 ! note!
end function plusone
end program plussing
Output
[funcf] plusone: 6
```

A function is not invoked with `call`, but rather through being used in an expression:

```fortran
|| if (test(3.0) .and. something_else) ... 
```

You now have the following cases to make the function known in the main program:

- If the function is in a `contains` section, its type is known in the main program.
- If the function is in a module (see section 37.2 below), it becomes known through a `use` statement.

**F77 note:** Without modules and `contains` sections, you need to declare the function type explicitly in the calling program. The safe way is through using an `interface` specification.

**Exercise 34.2.** Write a program that asks the user for a positive number; negative input should be rejected. Fill in the missing lines in this code fragment:
34.2. Return results

### Code:

```fortran
program readpos
    implicit none
    real(4) :: userinput
    print *, "Type a positive number:"
    userinput = read_positive()
    print *, "Thank you for", userinput
contains
    real(4) function read_positive()
        implicit none
        !! ...
        end function read_positive
end program readpos
```

### Output

```
[funcf] readpos:
Type a positive number:
No, not -5.00000000
No, not 0.00000000
No, not -3.14000010
Thank you for 2.48000002
```

34.2.1 The ‘result’ keyword

Apart from assigning to the function name, there is a second mechanism for returning a function result, namely through the `Result` keyword.

```fortran
function some_function() result(x)
    implicit none
    real :: x
    ! stuff
    x = ! some computation
end function
```

You see that here

- the assignment to the name is missing,
- the function name is not typed; but
- instead there is a typed local variable that is marked to be the result.

34.2.2 The ‘contains’ clause

#### Why a ‘contains’ clause?

**Program NoContains**

```fortran
implicit none
call DoWhat()
end Program NoContains
```

**Program ContainsScope**

```fortran
implicit none
call DoWhat()
contains
    subroutine DoWhat(i)
        implicit none
        integer :: i
        i = 5
    end subroutine DoWhat
end Program ContainsScope
```

Warning only, crashes.  

**Error, does not compile**

#### Why a ‘contains’ clause, take 2

**Program NoContains**

```fortran
implicit none
call DoWhat()
end Program NoContains
```

**Program ContainsScope**

```fortran
implicit none
call DoWhat()
contains
    subroutine DoWhat(i)
        implicit none
        integer :: i
        i = 5
    end subroutine DoWhat
end Program ContainsScope
```
34. Procedures

Code:

```
program NoContainTwo
  implicit none
  integer :: i = 5
  call DoWhat(i)
end Program NoContainTwo

subroutine DoWhat(x)
  implicit none
  real :: x
  print *, x
end subroutine DoWhat
```

At best compiler warning if all in the same file
For future reference: if you see very small floating point numbers, maybe you have made this error.

34.3 Arguments

**Procedure arguments**

Arguments are declared in procedure body:

```
subroutine f(x,y,i)
  implicit none
  integer, intent(in) :: i
  real(4), intent(out) :: x
  real(8), intent(inout) :: y
  x = 5; y = y+6
end subroutine f
```

Declaring the ‘intent’ is optional, but highly advisable.

**Parameter passing**

- Everything is passed by reference.
  Don’t worry about large objects being copied.
- Optional intent declarations:
  Use in, out, inout qualifiers to clarify semantics to compiler.

**Fortran nomenclature**

The term *dummy argument* is what Fortran calls the parameters in the procedure definition:

```
subroutine f(x)  ! 'x' is dummy argument
```

The arguments in the procedure call are the *actual arguments*:

```
call f(x)  ! 'x' is actual argument
```

**Intent checking**

Compiler checks your intent against your implementation. This code is not legal:
### 34.4. Types of procedures

Procedures that are in the main program (or another type of program unit), separated by a `contains` clause, are known as *internal procedures*. This is as opposed to *module procedures*.

There are also *statement functions*, which are single-statement functions, usually to identify commonly used complicated expressions in a program unit. Presumably the compiler will *inline* them for efficiency.

The *entry* statement is so bizarre that I refuse to discuss it.

### 34.5. More about arguments

#### Keyword arguments

- Use the name of the *formal parameter* as keyword.
- Keyword arguments have to come last.
34. Procedures

**Code:**

```fortran
! call say_xy(y=2,1) ! ILLEGAL
contains
    subroutine say_xy(x, y)
        implicit none
        integer, intent(in) :: x, y
        print *, "x=", x,", y=", y
    end subroutine say_xy
```

**Output**

<table>
<thead>
<tr>
<th>funcf</th>
<th>keyword:</th>
</tr>
</thead>
<tbody>
<tr>
<td>x=</td>
<td>1 , y=</td>
</tr>
<tr>
<td>x=</td>
<td>1 , y=</td>
</tr>
<tr>
<td>x=</td>
<td>1 , y=</td>
</tr>
<tr>
<td>x=</td>
<td>1 , y=</td>
</tr>
</tbody>
</table>

**Optional arguments**

- Extra specifier: **Optional**
- Presence of argument can be tested with **Present**

Fortran behaves slightly counterintuitive if you try to initialize local variables: they initialization is only executed once, and the second time you call the procedure it will have retained its previous value. (Technically: the variable has an implicit **Save** attribute.)

This may trip you up as the following example shows:

**Saved values**

Local variable is initialized only once, second time it uses its retained value.

```fortran
integer function maxof2(i, j)
    implicit none
    integer, intent(in) :: i, j
    integer :: max=0
    if (i>max) max = i
    if (j>max) max = j
    maxof2 = max
end function maxof2
```

**Output**

<table>
<thead>
<tr>
<th>funcf</th>
<th>save:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Comparing: 1 3</td>
<td></td>
</tr>
<tr>
<td>Comparing: -2 -4</td>
<td></td>
</tr>
</tbody>
</table>

Introduction to Scientific Programming
Chapter 35

String handling

35.1 String denotations

A string can be enclosed in single or double quotes. That makes it easier to have the other type in the string.

```
print *, 'This string was in single quotes'
print *, 'This string in single quotes contains a single '' quote'
print *, 'This string was in double quotes'
print *, 'This string in double quotes contains a double "" quote'
```

35.2 Characters

35.3 Strings

The length of a Fortran string is specified with the `len` keyword when the string is created:

```
character(len=50) :: mystring
```

```
mystring = "short string"
```

The `len` function also gives the length of the string, but note that that is the length with which it was allocated, not how much non-blank content you put in it.

```
character(len=12) :: strvar
!! ...
strvar = "word"
print *, len(strvar), len(trim(strvar))
```

```
Output
[strlen] strlen:
12 4
```

To get the more intuitive length of a string, that is, the location of the last non-blank character, you need to `trim` the string.

Intrinsic functions: `LEN(string), INDEX(substring,string), CHAR(int), ICHAR(char), TRIM(string)`
35. String handling

35.4 Strings versus character arrays

35.5 Formatted I/O

The default formatting uses quite a few positions for what can be small numbers. To indicate explicitly the formatting, for instance limiting the number of positions used for a number, or the whole and fractional part of a real number, you can use a format string.

For instance, you can use a letter followed by a digit to control the formatting width:

(In the last line, the format specifier was not wide enough for the data, so an asterisk was used as output.)

Let’s approach this semi-systematically.

35.5.1 Format letters

x : one space
x5 : five spaces
a5 : strings, five positions wide
i3 : integer, three positions wide
f5.2 : fixed point, 5 positions wide, 2 positions for fractional part
e13.8 : floating point, 13 positions wide, 8 positions for fractional part
b : binary
o : octal
z : hex
35.5.2 Repeating and grouping

If you want to display items of the same type, you can use a repeat count:

```
Code:

i = 12; j = 34
print *, i, j
print '(2i4)', i, j
print '(2i2)', i, j
```

Output

```
[iof] ii:
12 34
12 34
1234
```

You can mix variables of different types, as well as literal string, by separating them with commas. And you can group them with parentheses, and put a repeat count on those groups again:

```
Code:

i = 23; j = 45; k = 67
print '(i2,1x,i2)', i, j
print '("Numbers:" ,3(i1x,i2,"."))', i, j, k
```

Output

```
[iof] ij:
23 45
Numbers: 23. 45. 67.
```

To be precise, the format specifier is inside single quotes and parentheses, and consists of comma-separated specifications for a single item:

- `'a\_n'` specifies a string of \(n\) characters. If the actual string is longer, it is truncated in the output.
- `'i\_n'` specifies an integer of up to \(n\) digits. If the actual number takes more digits, it is rendered with asterisks. To use the minimum number of digits, use `'i0`.
- `'f\_m.n'` specifies a fixed point representation of a real number, with \(m\) total positions (including the decimal point) and \(n\) digits in the fractional part.
- `'e\_m.n'` Exponent representation.
- Strings can go into the format:
  ```
  print '("Result:" ,3f5.3)', x, y, z
  ```
- `'x'` for a space, `'/'` for newline

Putting a number in front of a single specifier indicates that it is to be repeated.

If the data takes more positions than the format specifier allows, a string of asterisks is printed:

```
Code:

do ipower=1,5
   print '(i3)', number
   number = 10*number
end do
```

Output

```
[iio] asterisk:
```

If you find yourself using the same format a number of times, you can give it a `label`:

```
print 10,"result:" ,x,y,z
10 format ('(a6,3f5.3)')
```

https://www.obliquity.com/computer/fortran/format.html

Format repetitions

```
print '( 3i4 )', ii, i2, i3
```
### 35. String handling

| `print ' ( 3(i2,"":f7.4) )', i1,r1,i2,r2,i3,r2` |

**Repeats and line breaks**

- If `abc` is a format string, then `10(abc)` gives 10 repetitions. There is no line break.
- If there is more data than specified in the format, the format is reused in a new print statement. This causes line breaks.
- The `/` (slash) specifier causes a line break.
- There may be a 80 character limit on output lines.

**Exercise 35.1.** Use formatted I/O to print the number 0 · · · 99 as follows:

<table>
<thead>
<tr>
<th>0 1 2 3 4 5 6 7 8 9</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 11 12 13 14 15 16 17 18 19</td>
</tr>
<tr>
<td>20 21 22 23 24 25 26 27 28 29</td>
</tr>
<tr>
<td>30 31 32 33 34 35 36 37 38 39</td>
</tr>
<tr>
<td>40 41 42 43 44 45 46 47 48 49</td>
</tr>
<tr>
<td>50 51 52 53 54 55 56 57 58 59</td>
</tr>
<tr>
<td>60 61 62 63 64 65 66 67 68 69</td>
</tr>
<tr>
<td>70 71 72 73 74 75 76 77 78 79</td>
</tr>
<tr>
<td>80 81 82 83 84 85 86 87 88 89</td>
</tr>
<tr>
<td>90 91 92 93 94 95 96 97 98 99</td>
</tr>
</tbody>
</table>
Chapter 36

Structures, eh, types

Fortran has structures for bundling up data, but there is no `struct` keyword; instead you declare both the structure type and variables of that `derived type` with the `type` keyword.

Now you need to

- Define the type to describe what’s in it;
- Declare variables of that type; and
- use those variables, but setting the type members or using their values.

**Type declaration**

Type name/End Type name block.

Member declarations inside the block:

```fortran
  type mytype
    integer :: number
    character :: name
    real(4) :: value
  end type mytype
```

**Creating a type structure**

Declare a type variable in the main program:

```
  Type(mytype) :: object1, object2
```

Initialize with type name:

```
  object1 = mytype( 1, 'my_name', 3.7 )
```

Copying:

```
  object2 = object1
```

**Member access**

Access structure members with `%`

```
  Type(mytype) :: typed_object
  typed_object%member = ....
```

**Example**
36. Structures, eh, types

```fortran
type point
    real :: x, y
end type point

type(point) :: p1, p2
p1 = point(2.5, 3.7)
p2 = p1
print *, p2%x, p2%y
```

Type definitions can go in the main program
(or use a module; see later)

You can have arrays of types:

```fortran
type(my_struct) :: data
type(my_struct), dimension(1) :: data_array
```

## Structures as procedure argument

Structures can be passed as procedure argument, just like any other datatype. This example:
- Takes a structure of `type(point)` as argument; and
- returns a `real(4)` result.
- The structure is declared as `intent(in)`.

### Function with structure argument:

```fortran
real(4) function length(p)
    implicit none
    type(point), intent(in) :: p

    length = sqrt( p%x**2 + p%y**2 )

end function length
```

### Function call

```fortran
print *, "Length:", length(p2)
```

### Exercise 36.1
Add a function `angle` that takes a `Point` argument and returns the angle of the x-axis and the line from the origin to that point.

![Diagram showing the angle α between the x-axis and the line from the origin to point P(x,y).]

Your program should read in the x, y values of the point and print out the angle in radians.

Bonus: can you print the angle as a fraction of π? So

\[(1,1) \Rightarrow 0.25\]

### Exercise 36.2
Write a program that has the following:
- A type `Point` that contains real numbers `x, y`;
- a type `Rectangle` that contains two `Points`, corresponding to the lower left and upper right point;
- a function \texttt{area} that has one argument: a \texttt{Rectangle}.

Your program should
- Accept two real numbers on one line, for the bottom left point;
- similarly, again on one line, the coordinates of the top right point; then
- print out the area of the (axi-parallel) rectangle defined by these two points.

Bonus points for using a module, double bonus points for using an object-oriented solution.
36. Structures, eh, types
Chapter 37

Modules

Fortran has a clean mechanism for importing data (including numeric constants such as $\pi$), functions, types that are defined in another file.

**Module definition**

Modules look like a program, but without main (only ‘stuff to be used elsewhere’):

```fortran
Module definitions
  type point
    real :: x, y
  end type point
  real(8), parameter :: pi = 3.14159265359
contains
  real(4) function length(p)
    implicit none
    type(point), intent(in) :: p
    length = sqrt( p%x**2 + p%y**2 )
  end function length
end Module definitions
```

Note also the numeric constant.

**Module use**

Module imported through `use` statement;
comes before `implicit none`
37. Modules

**Exercise 37.1.** Take exercise 36.2 and put all type definitions and all functions in a module.

### 37.1 Modules for program modularization

Modules are Fortran’s mechanism for supporting *separate compilation*: you can put your module in one file, your main program in another, and compile them separately.

**Separate compilation of modules**

Suppose program is split over two files: `theprogram.F90` and `themodule.F90`.

- Compile the module: `ifort -c themodule.F90`; this gives
  - an *object file* (extension: `.o`) that will be linked later, and
  - a module file `modulename.mod`.
- Compile the main program:
  - `ifort -c theprogram.F90` will *read* the `.mod` file; and finally
- Link the object files into an *executable*:
  - `ifort -o myprogram theprogram.o themodule.o`

The compiler is used as *linker*: there is no compiling in this step.

Important: the module needs to be compiled before any (sub)program that uses it.

### 37.2 Modules

A module is a container for definitions of subprograms and types, and for data such as constants and variables. A module is not a structure or object: there is only one instance.

What do you use a module for?

- Type definitions: it is legal to have the same type definition in multiple program units, but this is not a good idea. Write the definition just once in a module and make it available that way.
- Function definitions: this makes the functions available in multiple sources files of the same program, or in multiple programs.

---

**Code:**

```fortran
Program size
use definitions
implicit none
type (point) :: p1, p2
p1 = point (2.5, 3.7)
p2 = p1
print *, p2%x, p2%y
print *, "length:", length(p2)
print *, 2*pi
end Program size
```

**Output**

```
structf typemod:
  2.50000000  3.70000005
  length:    4.46542263
             6.2831854820251465
```

---

*Introduction to Scientific Programming*
• Define constants: for physics simulations, put all constants in one module and use that, rather than spelling out the constants each time.

• Global variables: put variables in a module if they do not fit an obvious scope.

  F77 note: Modules are much cleaner than common blocks. Do not use those.

Any routines come after the contains

A module is made available with the use keyword, which needs to go before the implicit none.

Module use

```
Program ModProgram
  use FunctionsAndValues
  implicit none
  print *, "Pi is:", pi
  call SayHi()
End Program ModProgram
```

Also possible:

```
Use mymodule, Only: func1, func2
Use mymodule, func1 => new_name1
```

By default, all the contents of a module is usable by a subprogram that uses it. However, a keyword private make module contents available only inside the module. You can make the default behaviour explicit by using the public keyword. Both public and private can be used as attributes on definitions in the module. There is a keyword protected for data members that are public, but can not be altered by code outside the module.

If you compile a module, you will find a .mod file in your directory. (This is little like a .h file in C++.)

If this file is not present, you can not use the module in another program unit, so you need to compile the file containing the module first.

Exercise 37.2 Write a module PointMod that defines a type Point and a function distance to make this code work:

```
use pointmod
implicit none
  type(Point) :: p1, p2
  real(*) :: p1x, p1y, p2x, p2y
  read *, p1x, p1y, p2x, p2y
  p1 = point(p1x, p1y)
p2 = point(p2x, p2y)
  print *, "Distance:", distance(p1, p2)
```

Put the program and module in two separate files and compile thusly:

```
ifort -g -c pointmod.F90
ifort -g -c pointmain.F90
ifort -g -o pointmain pointmod.o pointmain.o
```

Victor Eijkhout
37. Modules

37.2.1 Polymorphism

```fortran
module somemodule
  INTERFACE swap
  MODULE PROCEDURE swapreal, swapint, swaplog, swappoint
  END INTERFACE
  contains
     subroutine swapreal ...
     subroutine swappoint ...
     subroutine swapint ...
  end subroutine
end module
```

37.2.2 Operator overloading

```fortran
MODULE operator_overloading
  IMPLICIT NONE ...
  INTERFACE OPERATOR (+) ...
  MODULE PROCEDURE concat ...
  END INTERFACE

including the assignment operator:

```fortran
  INTERFACE ASSIGNMENT (=) ...
  subroutine_interface_body ...
  END INTERFACE
```

This mechanism can also be used for dot-operators:

```fortran
  INTERFACE OPERATOR (.DIST.) ...
  MODULE PROCEDURE calcdist ...
  END INTERFACE
```
Chapter 38

Classes and objects

38.1 Classes

Fortran classes are based on type objects, a little like the analogy between C++ struct and class constructs.

New syntax for specifying methods.

Object is type with methods

You define a type as before, with its data members, but now the type has a contains for the methods:

```
Module multmod
  type Scalar
    real(4) :: value
  contains
    procedure, public :: &
    printme, scaled
  end type Scalar

contains ! methods
  !! ...
end Module multmod
```

```
Program Multiply
  use multmod
  implicit none
  type(Scalar) :: x
  real(4) :: y
  x = Scalar(-3.14)
call x%printme()
y = x%scaled(2.)
print '(''f7.3'',''y
```

Method definition

```
subroutine printme(me)
  implicit none
  class(Scalar) :: me
  print '(''''The value is''',''f7.3'',''me%value''
end subroutine printme

function scaled(me,factor)
  implicit none
  class(Scalar) :: me
  real(4) :: scaled,factor
  scaled = me%value * factor
end function scaled
```

Methods have object as argument
You define functions that accept the type as first argument, but instead of declaring the argument as
\texttt{type}, you define it as \texttt{class}.

The members of the class object have to be accessed through the \% operator.

\begin{verbatim}
subroutine set(p, xu, yu)
    implicit none
    class(point) :: p
    real(8), intent(in) :: xu, yu
    p%x = xu; p%y = yu
end subroutine set
\end{verbatim}

\textbf{Class organization}

- You’re pretty much forced to use \texttt{Module}
- A class is a \texttt{Type} with a \texttt{contains} clause followed by \texttt{procedure} declaration
- Actual methods go in the \texttt{contains} part of the module
- \Rightarrow First argument of method is the object itself. \Leftarrow

\textbf{Point program}

\begin{verbatim}
Module PointClass
    Type, public :: Point
    real(8) :: x, y
    contains
    procedure, public :: &
    distance
End type Point
contains
    !! ... distance function ...
    !! ...
End Module PointClass

Program PointTest
    use PointClass
    implicit none
    type(Point) :: p1, p2
    p1 = point(1.d0,1.d0)
    p2 = point(4.d0,5.d0)
    print *, "Distance:", &
    p1%distance(p2)
End Program PointTest
\end{verbatim}

\textbf{Similarities and differences}

<table>
<thead>
<tr>
<th></th>
<th>C++</th>
<th>Fortran</th>
</tr>
</thead>
<tbody>
<tr>
<td>Members</td>
<td>in the object</td>
<td>in the ‘type’</td>
</tr>
<tr>
<td>Methods</td>
<td>in the object</td>
<td>interface: in the type</td>
</tr>
<tr>
<td></td>
<td></td>
<td>implementation: in the module</td>
</tr>
<tr>
<td>Constructor</td>
<td>default or explicit</td>
<td>none</td>
</tr>
<tr>
<td>object itself</td>
<td>‘this’</td>
<td>first argument</td>
</tr>
<tr>
<td>Class members</td>
<td>global variable</td>
<td>accessed through first arg</td>
</tr>
<tr>
<td>Object’s methods</td>
<td>period</td>
<td>percent</td>
</tr>
</tbody>
</table>

\textbf{Exercise 38.1.} Take the point example program and add a distance function:

\begin{verbatim}
Type(Point) :: p1, p2
! ... initialize p1, p2
dist = p1%distance(p2)
! ... print distance
\end{verbatim}
Exercise 38.2. Write a method `add` for the `Point` type:

```fortran
Type(Point) :: p1, p2, sum
!
! ... initialize p1, p2
sum = p1%add(p2)
```

What is the return type of the function `add`?

38.1.1 Final procedures: destructors

The Fortran equivalent of destructors is a final procedure, designated by the `final` keyword.

```fortran
contains
final :: &
print_final
end type Scalar
```

A final procedure has a single argument of the type that it applies to:

```fortran
subroutine print_final(me)
  implicit none
type(Scalar) :: me
  print '(On exit: value is', f7.3)', me%value
end subroutine print_final
```

The final procedure is invoked when a derived type object is deleted, except at the conclusion of a program:

```fortran
call tmp_scalar()
contains
subroutine tmp_scalar()
type(Scalar) :: x
real(4) :: y
x = Scalar(-3.14)
end subroutine tmp_scalar
```

38.1.2 Inheritance

More OOP

Inheritance:

```fortran
||type, extends(baseclas) :: derived_class
```

Pure virtual:

```fortran
||type, abstract
```

38. Classes and objects
Chapter 39

Arrays

Array handling in Fortran is similar to C++ in some ways, but there are differences, such as that Fortran indexing starts at 1, rather than 0. More importantly, Fortran has better handling of multi-dimensional arrays, and it is easier to manipulate whole arrays.

39.1 Static arrays

The preferred way for specifying an array size is:

**Fortran dimension**

Preferred way of creating arrays through `dimension` keyword:

```
real(8), dimension(100) :: x, y
```

One-dimensional arrays of size 100.

Older mechanism works too:

```
integer :: i(10,20)
```

Two-dimensional array of size 10 × 20.

These arrays are statically defined, and only live inside their program unit.

Such an array, with size explicitly indicated, is called a *static array* or *automatic array*. (See section 39.4 for dynamic arrays.)

**1-based Indexing**

Array indexing in Fortran is 1-based by default:

```
integer, parameter :: N=8
real(4), dimension(N) :: x
do i=1,N
  ... x(i) ... 
```

Note the use of `parameter`: *compile-time constant*

**Lower bound**

Unlike C++, Fortran can specify the lower bound explicitly:
real, dimension(-1:7) :: x
 do i=-1,7
   ... x(i) ...

Safer:

Code:

```
real, dimension(-1:7) :: array
integer :: idx
!! ...
 do idx=lbound(array,1),ubound(array,1)
   array(idx) = 1+idx/10.
   print *,array(idx)
 end do
```

Output

<table>
<thead>
<tr>
<th>[array] lbound:</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.899999976</td>
</tr>
<tr>
<td>1.000000000</td>
</tr>
<tr>
<td>1.10000002</td>
</tr>
<tr>
<td>1.20000005</td>
</tr>
<tr>
<td>1.29999995</td>
</tr>
<tr>
<td>1.39999998</td>
</tr>
<tr>
<td>1.50000000</td>
</tr>
<tr>
<td>1.60000002</td>
</tr>
<tr>
<td>1.70000005</td>
</tr>
</tbody>
</table>

Such arrays, as in C++, obey the scope: they disappear at the end of the program or subprogram.

39.1.1 Initialization

There are various syntaxes for array initialization, including the use of implicit do-loops:

Array initialization

```
real, dimension(5) :: real5 = [ 1.1, 2.2, 3.3, 4.4, 5.5 ]
!! ...
real5 = [ (1.01*i,i=1,size(real5,1)) ]  
!! ...
real5 = (/ 0.1, 0.2, 0.3, 0.4, 0.5 /)
```

39.1.2 Array sections

Fortran is more sophisticated than C++ in how it can handle arrays as a whole. For starters, you can assign one array to another:

```
real*8, dimension(10) :: x,y
x = y
```

This obviously requires the arrays to have the same size. You can assign subarrays, or array sections, as long as they have the same shape. This uses a colon syntax.

Array sections

- : to get all indices,
- :n to get indices up to n,
- n: to get indices n and up.
- m:n indices in range m, ..., n.

Use of sections
Exercise 39.1. Code out the above array assignment with an explicit, indexed loop. Do you get the same output? Why? What conclusion do you draw about internal mechanisms used in array sections?

The above exercise illustrates a point about the semantics of array operations: an array statement behaves as if all inputs are gathered together before any results are stored. Conceptually, it is as if the right-hand side is assembled and copied to some temporary locations before being written to the left-hand side. In practice, this may require large temporary arrays (and negatively affect performance by lessening locality) so you hope that the compiler does something smarter. However, the exercise showed that an array assignment can not trivially be converted to a simply loop.

Exercise 39.2. Can you formalize the sort of array statement for which a simple translation to a loop changes the semantics? (In compiler terminology this is called a dependence.)

Array operations can be more sophisticated than assigning to a whole array or a section of it. For instance, you can use a stride:

### Strided sections

Exercise 39.3. \[ y_i = \frac{x_i + x_{i+1}}{2} \]

Code \[ y_i = \frac{x_i + x_{i+1}}{2} \]

First with a do loop; then
in a single array assignment statement by using sections.
Initialize the array $x$ with values that allow you to check the correctness of your code.

### 39.1.3 Integer arrays as indices

**Index arrays**

```fortran
integer, dimension(4) :: i = [2, 4, 6, 8]
real(4), dimension(10) :: x
print *, x(i)
```

### 39.2 Multi-dimensional

Arrays above had ‘rank one’. The rank is defined as the number of indices you need to address the elements. Calling this the ‘dimension’ of the array can be confusing, but we will talk about the first and second dimension of the array.

A rank-two array, or matrix, is defined like this:

**Multi-dimension arrays**

```fortran
real(8), dimension(20,30) :: array
array(i,j) = 5./2
```

With multidimensional arrays we have to worry how they are stored in memory. Are they stored row-by-row, or column-by-column? In Fortran the latter choice, also known as column-major storage, is used; see figure 39.1.

**Figure 39.1: Column-major storage in Fortran**

To traverse the elements as they are stored in memory, you would need the following code:

```fortran
do col=1, size(A,2)
do row=1, size(A,1)
.... A(row, col) .....  
end do 
end do
```

This is sometimes described as ‘First index varies quickest’.

---

**Introduction to Scientific Programming**
Exercise 39.4. Can you describe in words how memory elements are access if you would write:

\[
\begin{align*}
&\text{do } \text{row}=1, \text{size}(A,1) \\
&\quad \text{do } \text{col}=1, \text{size}(A,2) \\
&\quad \quad \text{... } A(\text{row}, \text{col}) \quad \text{...} \\
&\text{end do} \\
&\text{end do}
\end{align*}
\]

You can make sections in multi-dimensional arrays: you need to indicate a range in all dimensions.

**Array sections in multi-D**

\[
\begin{align*}
&\text{real(8), dimension(10) :: } a, b \\
&\quad a(1:9) = b(2:10)
\end{align*}
\]

or

\[
\begin{align*}
&\text{logical, dimension(25,3) :: } a \\
&\quad \text{logical, dimension(25) :: } b \\
&\quad a(:,2) = b
\end{align*}
\]

You can also use strides.

**Array printing**

Fill array by rows:

\[
\begin{array}{cccc}
1 & 2 & \ldots & N \\
N + 1 & \ldots & \\
& \vdots & \\
&MN \\
\end{array}
\]

**Code:**

\[
\begin{align*}
&\text{do } i=1,M \\
&\quad \text{do } j=1,N \\
&\quad \quad \text{rect}(i,j) = \text{count} \\
&\quad \quad \text{count} = \text{count}+1 \\
&\quad \text{end do} \\
&\text{end do} \\
&\text{print *, rect}
\end{align*}
\]

Output:

\[
\text{[arrayf] printarray:} \\
\begin{array}{cc}
1.00000000 & 6.00000000 \\
\end{array}
\]

**39.2.1 Querying an array**

We have the following properties of an array:

- The bounds are the lower and upper bound in each dimension. For instance, after

\[
\text{integer, dimension(-1:1,-2:2) :: symm}
\]

the array `symm` has a lower bound of \(-1\) in the first dimension and \(-2\) in the second. The functions `Lbound` and `Ubound` give these bounds as array or scalar:
39. Arrays

\[
\text{array_of_lower} = \text{Lbound}(\text{symm}) \\
\text{upper_in_dim_2} = \text{Ubound}(\text{symm}, 2)
\]

**Code:**

```plaintext
real(8), dimension(2:N+1) :: Afrom2 = &
  ! ... 
lo = lbound(Afrom1,1)
hi = ubound(Afrom1,1)
print *, lo, hi
print '(i3,":\",f5.3)', 
   (i,Afrom1(i),i=lo,hi)
```

**Output**

```plaintext
arrayf] fsection2:
   1     5
1:1.000 
2:2.000 
3:3.000 
4:4.000 
5:5.000 
```

- The **extent** is the number of elements in a certain dimension, and the **shape** is the array of extents.
- The **size** is the number of elements, either for the whole array, or for a specified dimension.

**39.2.2 Reshaping**

**RESHAPE**

\[
\text{array} = \text{RESHAPE} ( \text{list,shape} )
\]

**Example:**

```plaintext
\text{square} = \text{reshape} ( (/\{i,i=1,16\}/,(/4,4/) )
```

**SPREAD**

\[
\text{array} = \text{SPREAD} ( \text{old,dim,copies} )
\]

**39.3 Arrays to subroutines**

Subprogram needs to know the shape of an array, not the actual bounds:

**Pass array: main program**

Passing array as one symbol:
### 39.4 Allocatable arrays

Static arrays are fine at small sizes. However, there are two main arguments against using them at large sizes.

- Since the size is explicitly stated, it makes your program inflexible, requiring recompilation to run it with a different problem size.
- Since they are allocated on the so-called stack, making them too large can lead to stack overflow.

A better strategy is to indicate the shape of the array, and use `allocate` to specify the size later, presumably in terms of run-time program parameters.

#### Array allocation

```fortran
real(8), dimension(:), allocatable :: x, y
n = 100
allocate(x(n), y(n))
```

You can `deallocate` the array when you don’t need the space anymore.
If you are in danger of running out of memory, it can be a good idea to add a `stat=ierr` clause to the `allocate` statement:

```fortran
integer :: ierr
allocate( x(n), stat=ierr )
if ( ierr/=0 ) ! report error
```

Has an array been allocated:

```fortran
Allocated( x ) ! returns logical
```

Allocatable arrays are automatically deallocated when they go out of scope. This prevents the memory leak problems of C++.

Explicit deallocate:

```fortran
deallocate(x)
```

### 39.4.1 Returning an allocated array

In an effort to keep the main program nice and abstract, you may want to delegate the `allocate` statement to a procedure. In case of a `Subroutine`, you can pass the (unallocated) array as a parameter. But can you return it from a `Function`?

This requires the `Result` keyword (section 34.2.1):

```fortran
function create_array(n) result(v)
    implicit none
    integer, intent(in) :: n
    real, dimension(:), allocatable :: v
    integer :: i
    allocate(v(n))
    v = [ (i+.5,i=1,n) ]
end function create_array
```

### 39.5 Array output

Use implicit do-loops; section 32.3.

### 39.6 Operating on an array

#### 39.6.1 Arithmetic operations

Between arrays of the same shape:

```fortran
A = B+C
D = D*E
```

(where the multiplication is by element).
39.6. Operating on an array

39.6.2 Intrinsic functions

The following intrinsic functions are available for arrays:

**Array intrinsics**

- **Abs** creates the matrix of pointwise absolute values.
- **MaxVal** finds the maximum value in an array.
- **MinVal** finds the minimum value in an array.
- **Sum** returns the sum of all elements.
- **Product** returns the product of all elements.
- **MaxLoc** returns the index of the maximum element.
- **MinLoc** returns the index of the minimum element.
- **MatMul** returns the matrix product of two matrices.
- **Dot_Product** returns the dot product of two arrays.
- **Transpose** returns the transpose of a matrix.
- **Cshift** rotates elements through an array.

**Multi-dimensional intrinsics**

- Functions such as **Sum** operate on a whole array by default.
- To restrict such a function to one subdimension add a keyword parameter **DIM**:
  
  \[ s = \text{Sum}(A, \text{DIM}=1) \]

  where the keyword is optional.
- Likewise, the operation can be restricted to a **MASK**:

  \[ s = \text{Sum}(A, \text{MASK}=B) \]

**Exercise 39.5.** The 1-norm of a matrix is defined as the maximum of all sums of absolute values in any column:

\[
\| A \|_1 = \max_j \sum_i |A_{ij}|
\]

while the infinity-norm is defined as the maximum row sum:

\[
\| A \|_\infty = \max_i \sum_j |A_{ij}|
\]

Compute these norms using array functions as much as possible, that is, try to avoid using loops.

For bonus points, write Fortran **Functions** that compute these norms.

**Exercise 39.6.** Compare implementations of the matrix-matrix product.

1. Write the regular \( i, j, k \) implementation, and store it as reference.
2. Use the **DOT_PRODUCT** function, which eliminates the \( k \) index. How does the timing change? Print the maximum absolute distance between this and the reference result.
3. Use the **MATMUL** function. Same questions.
Bonusc question: investigate the \( j, k, i \) and \( i, k, j \) variants. Write them both with array sections and individual array elements. Is there a difference in timing?

Does the optimization level make a difference in timing?

39.6.3 Restricting with \texttt{where}

If an array operation should not apply to all elements, you can specify the ones it applies to with a \texttt{where} statement.

**Operate where**

\[
\texttt{where } ( A<0 ) B = 0
\]

**Full form:**

\[
\texttt{WHERE } ( \texttt{logical argument} ) \quad \texttt{sequence of array statements} \\
\texttt{ELSEWHERE} \quad \texttt{sequence of array statements} \\
\texttt{END WHERE}
\]

39.6.4 Global condition tests

Reduction of a test on all array elements: \texttt{all}

\[
\begin{array}{l}
\texttt{REAL(8), dimension(N,N) : : A} \\
\texttt{LOGICAL : : positive,positive_row(N),positive_col(N)} \\
\texttt{positive = \texttt{ALL}( A>0) } \\
\texttt{positive_row = \texttt{ALL}( A>0,1) } \\
\texttt{positive_col = \texttt{ALL}( A>0,2) }
\end{array}
\]

**Exercise 39.7.** Use array statements (that is, no loops) to fill a two-dimensional array \( A \) with random numbers between zero and one. Then fill two arrays \( A_{\text{big}} \) and \( A_{\text{small}} \) with the elements of \( A \) that are great than 0.5, or less than 0.5 respectively:

\[
A_{\text{big}}(i,j) = \begin{cases} A(i,j) & \text{if } A(i,j) \geq 0.5 \\ 0 & \text{otherwise} \end{cases}
\]

\[
A_{\text{small}}(i,j) = \begin{cases} 0 & \text{if } A(i,j) \geq 0.5 \\ A(i,j) & \text{otherwise} \end{cases}
\]

Using more array statements, add \( A_{\text{big}} \) and \( A_{\text{small}} \), and test whether the sum is close enough to \( A \).

Similar to \texttt{all}, there is a function \texttt{any} that tests if any array element satisfies the test.

\[
\texttt{if } ( \texttt{Any} (A-B) > 0)
\]
39.7  Array operations

39.7.1  Loops without looping

In addition to ordinary do-loops, Fortran has mechanisms that save you typing, or can be more efficient in some circumstances.

39.7.1.1  Slicing

If your loop assigns to an array from another array, you can use section notation:

\[
\begin{align*}
    a(1:n) &= b(1:n) \\
    c(1:n) &= d(2:n+1)
\end{align*}
\]

39.7.1.2  ‘forall’ keyword

The `forall` keyword also indicates an array assignment:

\[
\begin{align*}
    \text{forall} (i=1:n) \\
    a(i) &= b(i) \\
    c(i) &= d(i+1)
\end{align*}
\]

You can tell that this is for arrays only, because the loop index has to be part of the left-hand side of every assignment.

What happens if you apply `forall` to a statement with loop-carried dependencies? Consider first the traditional loops

\[
\begin{align*}
    A &= [1,2,3,4,5] \\
    \text{do } i=1,4 \Rightarrow A(i+1) = A(i) \Rightarrow \text{end do} \\
    \text{print } '(5(i2x))', A
\end{align*}
\]

Can you predict the output? Now consider the following:

<table>
<thead>
<tr>
<th>Code:</th>
<th>Output</th>
</tr>
</thead>
</table>
| \[
\begin{align*}
    A &= [1,2,3,4,5] \\
    \text{forall } (i=1:4) \\
    A(i+1) &= A(i) \\
    \text{end forall} \\
    \text{print } '(5(i2x))', A
\end{align*}
\] | \[
\begin{align*}
    A &= [1,2,3,4,5] \\
    \text{forall } (i=1:4) \\
    A(i+1) &= A(i) \\
    \text{end forall} \\
    \text{print } '(5(i2x))', A
\end{align*}
\] |

<table>
<thead>
<tr>
<th>Code:</th>
<th>Output</th>
</tr>
</thead>
</table>
| \[
\begin{align*}
    A &= [1,2,3,4,5] \\
    \text{do } i=4,1,-1 \Rightarrow A(i+1) = A(i) \Rightarrow \text{end do} \\
    \text{print } '(5(i2x))', A
\end{align*}
\] | \[
\begin{align*}
    A &= [1,2,3,4,5] \\
    \text{do } i=4,1,-1 \Rightarrow A(i+1) = A(i) \Rightarrow \text{end do} \\
    \text{print } '(5(i2x))', A
\end{align*}
\] |
39. Arrays

What does this tell you about the execution?

In other words, this mechanism is prone to misunderstanding and therefore now deprecated. It is not a parallel loop! For that, the following mechanism is preferred.

39.7.1.3 Do concurrent

Do concurrent

The do concurrent is a true do-loop. With the concurrent keyword the user specifies that the iterations of a loop are independent, and can therefore possibly be done in parallel:

```plaintext
do concurrent (i=1:n)
  a(i) = b(i)
  c(i) = d(i+1)
end do
```

(Do not use for all)

39.7.2 Loops without dependencies

Here are some illustrations of simple array copying with the above mechanisms.

```plaintext
do i=2,n
  counted(i) = 2*counting(i-1)
end do
```

<table>
<thead>
<tr>
<th>Original</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Recursive</td>
<td>0</td>
<td>2</td>
<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
<td>12</td>
<td>14</td>
<td>16</td>
<td>18</td>
</tr>
</tbody>
</table>

```plaintext
counted(2:n) = 2*counting(1:n-1)
```

<table>
<thead>
<tr>
<th>Original</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>

<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
<td>12</td>
<td>14</td>
<td>16</td>
<td>18</td>
</tr>
</tbody>
</table>

```plaintext
forall (i=2:n)
  counted(i) = 2*counting(i-1)
end forall
```

<table>
<thead>
<tr>
<th>Original</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>

<td>2</td>
<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
<td>12</td>
<td>14</td>
<td>16</td>
<td>18</td>
</tr>
</tbody>
</table>

```plaintext
do concurrent (i=2:n)
  counted(i) = 2*counting(i-1)
end do
```

<table>
<thead>
<tr>
<th>Original</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Concurrent</td>
<td>0</td>
<td>2</td>
<td>4</td>
<td>6</td>
<td>8</td>
<td>10</td>
<td>12</td>
<td>14</td>
<td>16</td>
<td>18</td>
</tr>
</tbody>
</table>

Exercise 39.8. Create arrays A, C of length 2N, and B of length N. Now implement

\[ B_i = (A_{2i} + A_{2i+1})/2, \quad i = 1, \ldots, N \]
and

\[ C_i = A_{i/2}, \quad i = 1, \ldots, 2N \]

using all four mechanisms. Make sure you get the same result every time.

### 39.7.3 Loops with dependencies

For parallel execution of a loop, all iterations have to be independent. This is not the case if the loop has a *recurrence*, and in this case, the ‘do concurrent’ mechanism is not appropriate. Here are the above four constructs, but applied to a loop with a dependence.

**Original**

<table>
<thead>
<tr>
<th>i</th>
<th>1</th>
<th>2</th>
<th>3</th>
<th>4</th>
<th>5</th>
<th>6</th>
<th>7</th>
<th>8</th>
<th>9</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>counting(i)</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>8</td>
<td>16</td>
<td>32</td>
<td>64</td>
<td>128</td>
<td>256</td>
<td>512</td>
</tr>
</tbody>
</table>

**Recursive**

<table>
<thead>
<tr>
<th>i</th>
<th>1</th>
<th>2</th>
<th>4</th>
<th>8</th>
<th>16</th>
<th>32</th>
<th>64</th>
<th>128</th>
<th>256</th>
<th>512</th>
</tr>
</thead>
<tbody>
<tr>
<td>counting(i)</td>
<td>1</td>
<td>2</td>
<td>4</td>
<td>8</td>
<td>16</td>
<td>32</td>
<td>64</td>
<td>128</td>
<td>256</td>
<td>512</td>
</tr>
</tbody>
</table>

The slicing version of this:

<table>
<thead>
<tr>
<th>counting(2:n)</th>
<th>2*counting(1:n-1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original</td>
<td>1 2 3 4 5 6 7 8 9 10</td>
</tr>
<tr>
<td>Section</td>
<td>1 2 4 6 8 10 12 14 16 18</td>
</tr>
</tbody>
</table>

acts as if the right-hand side is saved in a temporary array, and subsequently assigned to the left-hand side.

Using ‘forall’ is equivalent to slicing:

<table>
<thead>
<tr>
<th>forall (i=2:n)</th>
<th>2*counting(i-1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original</td>
<td>1 2 3 4 5 6 7 8 9 10</td>
</tr>
<tr>
<td>Forall</td>
<td>1 2 4 6 8 10 12 14 16 18</td>
</tr>
</tbody>
</table>

On the other hand, ‘do concurrent’ does not use temporaries, so it is more like the sequential version:

<table>
<thead>
<tr>
<th>do concurrent (i=2:n)</th>
<th>2*counting(i-1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Original</td>
<td>1 2 3 4 5 6 7 8 9 10</td>
</tr>
<tr>
<td>Concurrent</td>
<td>1 2 4 8 16 32 64 128 256 512</td>
</tr>
</tbody>
</table>

Note that the result does not have to be equal to the sequential execution: the compiler is free to rearrange the iterations any way it sees fit.

### 39.8 Review questions
Exercise 39.9. Let the following declarations be given, and assume that all arrays are properly initialized:

\[
\begin{align*}
    \text{real} & \quad ::= \ x \\
    \text{real, dimension}(10) & \quad ::= \ a, \ b \\
    \text{real, dimension}(10,10) & \quad ::= \ c, \ d
\end{align*}
\]

Comment on the following lines: are they legal, if so what do they do?
1. \( a = b \)
2. \( a = x \)
3. \( a(1:10) = c(1:10) \)

How would you:
1. Set the second row of \( c \) to \( b \)?
2. Set the second row of \( c \) to the elements of \( b \), last-to-first?
Chapter 40

Pointers

Pointers in C/C++ are based on memory addresses; Fortran pointers on the other hand, are more abstract.

40.1 Basic pointer operations

Pointers are aliases
- Pointer points at an variable
- Access variable through pointer
- You can change what variable the pointer points at.

Pointers could also be called ‘aliases’: they act like an alias for an variable of elementary or derived data type. You can access the variable through the alias. The difference with actually using the variable, is that you can decide what variable the pointer points at.

Dereferencing

Fortran pointers are often automatically dereferenced: if you print a pointer you print the variable it references, not some representation of the pointer.

```
real, target :: x
real, pointer :: that_real

x = 1.2
that_real => x
print *, that_real
```

Output

```
[pointerf] basicp:
1.20000005
```

The `pointer` definition
```
||real,pointer :: point_at_real
```
defined a pointer that can point at a real variable.

Setting the pointer
- You have to declare that a variable is pointable:
```
||real,target :: x
```
- Set the pointer with => notation (New! Note!):
Pointers

Now using `point_at_real` is the same as using `x`.

| `print *`, `point_at_real` | will print the value of x |

Pointers can not just point at anything: the thing pointed at needs to be declared as `target`.

| `real`, `target` | :: `x` |

and you use the `=` operator to let a pointer point at a target:

| `point_at_real` | => `x` |

If you use a pointer, for instance to print it

| `print *`, `point_at_real` |

it behaves as if you were using the value of what it points at.

**Pointer example**

### Code:

```cpp
real, target :: x, y
real, pointer :: that_real

x = 1.2
y = 2.4
that_real => x
print *, that_real
that_real => y
print *, that_real
y = x
print *, that_real
```

### Output

```
[pointerf] realp:
1.20000005
2.40000010
1.20000005
```

1. The pointer points at `x`, so the value of `x` is printed.
2. The pointer is set to point at `y`, so its value is printed.
3. The value of `y` is changed, and since the pointer still points at `y`, this changed value is printed.

**Assign pointer from other pointer**

```cpp
real, pointer :: point_at_real, also_point
point_at_real => x
also_point => point_at_real
```

Now you have two pointers that point at `x`.

**Very important to use the `=>`, otherwise strange memory errors**

If you have two pointers

| `real, pointer` | :: `point_at_real`, `also_point` |

you can make the target of the one to also be the target of the other:

| `also_point` | => `point_at_real` |
This is not a pointer to a pointer: it assigns the target of the right-hand side to be the target of the left-hand side.

Assignment subtleties

Assign underlying variables:

```
real, target :: x, y
real, pointer :: p1, p2
```

```
x = 1.2
p1 => x
p2 => y
p2 = p1 ! same as y=x
print *, p2 ! same as print y
```

Crash because lhs pointer unassociated:

```
real, target :: x
real, pointer :: p1, p2
```

```
x = 1.2
p1 => x
p2 = p1
```

```
print *, p2
```

Exercise 40.1. Write a routine that accepts an array and a pointer, and on return has that pointer pointing at the largest array element:

```
real, dimension(10), target :: array &
    = [1.1, 2.2, 3.3, 4.4, 5.5, &
        9.9, 8.8, 7.7, 6.6, 0.0]
real, pointer :: biggest_element

print '(10f5.2)', array
call SetPointer(array, biggest_element)
print *, "Biggest element is", biggest_element
biggest_element = 0
print '(10f5.2)', array
```

Output

```
[pointerf] arpointf:
1.10 2.20 3.30 4.40 5.50 9.90 8.80 7.70 6.60 0.00
Biggest element is 9.89999962
1.10 2.20 3.30 4.40 5.50 0.00 8.80 7.70 6.60 0.00
```

Pointer status

- **Nullify**: zero a pointer
- **Associated**: test whether assigned
40. Pointers

Code:

```fortran
real, target :: x
real, pointer :: realp

print *, "Pointer starts as not set"
if (.not. associated(realp)) &
  print *, "Pointer not associated"
x = 1.2
print *, "Set pointer"
realp = x
if (associated(realp)) &
  print *, "Pointer points"
print *, "Unset pointer"
nullify(realp)
if (.not. associated(realp)) &
  print *, "Pointer not associated"
```

Output

```
[printf statusp:
  Pointer starts as not set
  Pointer not associated
  Set pointer
  Pointer points
  Unset pointer
  Pointer not associated
```

Dynamic allocation

Pointers are Fortran’s way of making dynamic allocation:

```fortran
Integer, Pointer, Dimension(:) :: array_point
Allocate( array_point(100) )
```

This is automatically deallocated when control leaves the scope. No memory leaks.

40.2 Pointers and arrays

You can set a pointer to an array element or a whole array.

```fortran
real(8), dimension(10), target :: array
real(8), pointer :: element_ptr
real(8), pointer, dimension(:) :: array_ptr

element_ptr => array(2)
array_ptr   => array
```

More surprising, you can set pointers to array slices:

```fortran
array_ptr => array(2:)
array_ptr => array(1:size(array):2)
```

In case you’re wondering, this does not create temporary arrays, but the compiler adds descriptions to the pointers, to translate code automatically to strided indexing.

40.3 Example: linked lists

For pictures of linked lists, see section 65.1.2.
Linked list

- Linear data structure
- more flexible for insertion / deletion
- ... but slower in access

One of the standard examples of using pointers is the linked list. This is a dynamic one-dimensional structure that is more flexible than an array. Dynamically extending an array would require re-allocation, while in a list an element can be inserted.

Exercise 40.2. Using a linked list may be more flexible than using an array. On the other hand, accessing an element in a linked list is more expensive, both absolutely and as order-of-magnitude in the size of the list.

Make this argument precise.

Linked list datatypes

- Node: value field, and pointer to next node.
- List: pointer to head node.

```plaintext
type node
  integer :: value
  type(node), pointer :: next
end type node

type list
  type(node), pointer :: head
end type list

type(list) :: the_list
nullify(the_list%head)
```

A list is based on a simple data structure, a node, which contains a value field and a pointer to another node.

By way of example, we create a dynamic list of integers, sorted by size. To maintain the sortedness, we need to append or insert nodes, as required.

Here are the basic definitions of a node, and a list which is basically a repository for the head node:
**List initialization**

First element becomes the list head:

```plaintext
allocate(new_node)
new_node\%value = value
nullify(new_node\%next)
the_list\%head => new_node
```

Initially, the list is empty, meaning that the ‘head’ pointer is un-associated. The first time we add an element to the list, we create a node and assign it as the head of the list:

```plaintext
allocate(new_node)
new_node\%value = value
nullify(new_node\%next)
the_list\%head => new_node
```

**Attaching a node**

Keep the list sorted: new largest element attached at the end.

```plaintext
allocate(new_node)
new_node\%value = value
nullify(new_node\%next)
current\%next => new_node
```

**Exercise 40.3.** Write function `attach` that takes an integer, and attaches a new node at the end of the list with that value.

Adding a value to a list can be done two ways. If the new element is larger than all elements in the list, a new node needs to be appended to the last one. Let’s assume we have managed to let `current` point at the last node of the list, then here is how to attaching a new node from it:

```plaintext
allocate(new_node)
new_node\%value = value
nullify(new_node\%next)
current\%next => new_node
```

**Inserting 1**

Find the insertion point:

```plaintext
current => the_list\%head ; nullify(previous)
do while ( current\%value<value &
    .and. associated(current\%next) )
    previous => current
    current => current\%next
end do
```

Inserting an element in the list is harder. First of all, you need to find the two nodes, `previous` and `current`, between which to insert the new node:

```plaintext
current => the_list\%head ; nullify(previous)
do while ( current\%value<value &
    .and. associated(current\%next) )
```
40.3. Example: linked lists

The actual insertion requires rerouting some pointers:

```markdown
previous => current
current => current%next
end do
```

Inserting 2

Exercise 40.4. Write a print function for the linked list.
For the simplest solution, print each element on a line by itself.

More sophisticated: use the Write function and the advance keyword:

```markdown
write(*,'(i1",")',advance="no") current%value
```

Exercise 40.5. Write a length function for the linked list.
Try it both with a loop, and recursively.
Chapter 41

Input/output

41.1 Types of I/O

Fortran can deal with input/output in ASCII format, which is called formatted I/O, and binary, or unformatted I/O. Formatted I/O can use default formatting, but you can specify detailed formatting instructions, in the I/O statement itself, or separately in a Format statement.

Fortran I/O can be described as list-directed I/O: both input and output commands take a list of item, possibly with formatting specified.

<table>
<thead>
<tr>
<th>I/O commands</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Print simple output to terminal</td>
</tr>
<tr>
<td>• Write output to terminal or file (‘unit’)</td>
</tr>
<tr>
<td>• Read input from terminal or file</td>
</tr>
<tr>
<td>• Open, Close for files and streams</td>
</tr>
<tr>
<td>• Format format specification that can be used in multiple statements.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Formatted and unformatted I/O</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Formatted: ascii output. This is good for reporting, but not for numeric data storage.</td>
</tr>
<tr>
<td>• Unformatted: binary output. Great for further processing of output data.</td>
</tr>
<tr>
<td>• Beware: binary data is machine-dependent. Use hdf5 for portable binary.</td>
</tr>
</tbody>
</table>

41.2 Print to terminal

The simplest command for outputing data is print.

\[
\text{print } *, \text{"The result is"}, \text{result}
\]

In its easiest form, you use the star to indicate that you don’t care about formatting; after the comma you can then have any number of comma-separated strings and variables.

41.2.1 Print on one line

The statement

\[
\text{print } *, \text{item1, item2, item3}
\]

will print the items on one line, as far as the line length allows.
Implicit do loops

Parametrized printing with an implicit do loop:

```fortran
print *, ( i*i, i=1, n )
```

All values will be printed on the same line.

41.2.2 Printing arrays

If you print a variable that is an array, all its elements will be printed, in column-major ordering if the array is multi-dimensional.

You can also control the printing of an array by using an implicit do loop:

```fortran
print *, ( A(i), i=1, n )
```

41.3 File and stream I/O

If you want to send output anywhere else than the terminal screen, you need the `write` statement, which looks like:

```fortran
write (unit, format) data
```

where `format` and `data` are as described above. The new element is the `unit`, which is a numerical indication of an output device, such as a file.

41.3.1 Units

```fortran
Open(11)
```

will result in a file with a name typically `fort11`.

```fortran
Open(11, FILE="filename")
```

Many other options for error handling, new vs old file, etc.

After this:

```fortran
Write (11, fmt) data
```

Again options for errors and such.

41.3.2 Other write options

```fortran
write(unit, fmt, ADVANCE="no") data
```

will not issue a newline.
41.4 Unformatted output

So far we have looked at ascii output, which is nice to look at for a human, but is not the right medium to communicate data to another program.

- Ascii output requires time-consuming conversion.
- Ascii rendering leads to loss of precision.

Therefore, if you want to output data that is later to be read by a program, it is best to use binary output or unformatted output, sometimes also called raw output.

**Unformatted output**

Indicated by lack of format specification:

```
||write (*) data
```

Note: may not be portable between machines.
41. Input/output
Chapter 42

Leftover topics

42.1 Interfaces

If you want to use a procedure in your main program, the compiler needs to know the signature of the procedure: how many arguments, of what type, and with what intent. You have seen how the `contains` clause can be used for this purpose if the procedure resides in the same file as the main program.

If the procedure is in a separate file, the compiler does not see definition and usage in one go. To allowed the compiler to do checking on proper usage, we can use an interface block. This is placed at the calling site, declaring the signature of the procedure.

Main program:

```fortran
interface
  function f(x,y) 
  real*8 :: f 
  real*8, intent(in) :: x, y 
end function f
end interface 
real*8 :: in1=1.5, in2=2.6, result 
result = f(in1,in2)
```

Procedure:

```fortran
function f(x,y) 
implicit none 
real*8 :: f 
real*8, intent(in) :: x,y
```

The interface block is not required (an older external mechanism exists for functions), but is recommended. It is required if the function takes function arguments.

42.1.1 Polymorphism

The interface block can be used to define a generic function:

```fortran
interface f
function f1( ..... )
function f2( ..... )
end interface f
```

where \( f_1, f_2 \) are functions that can be distinguished by their argument types. The generic function \( f \) then becomes either \( f_1 \) or \( f_2 \) depending on what type of argument it is called with.
42. Leftover topics

42.2 Random numbers

In this section we briefly discuss the Fortran random number generator. The basic mechanism is through the library subroutine `random_number`, which has a single argument of type REAL with INTENT(OUT):

```fortran
real(4) :: randomfraction
call random_number(randomfraction)
```

The result is a random number from the uniform distribution on [0, 1).

Setting the random seed is slightly convoluted. The amount of storage needed to store the seed can be processor and implementation-dependent, so the routine `random_seed` can have three types of named argument, exactly one of which can be specified at any one time. The keyword can be:

- SIZE for querying the size of the seed;
- PUT for setting the seed; and
- GET for querying the seed.

A typical fragment for setting the seed would be:

```fortran
integer :: seedsize
integer, dimension(:), allocatable :: seed

call random_seed(size=seedsize)
allocate(seed(seedsize))
seed(:) = ! your integer seed here
call random_seed(put=seed)
```

42.3 Timing

Timing is done with the `system_clock` routine.

- This call gives an integer, counting clock ticks.
- To convert to seconds, it can also tell you how many ticks per second it has: its timer resolution.

```fortran
integer :: clockrate,clock_start,clock_end
call system_clock(count_rate=clockrate)
print *,"Ticks per second: ",clockrate

call system_clock(clock_start)
! code
call system_clock(clock_end)
print *,"Time: ",clock_end-clock_start)/REAL(clockrate)
```
Chapter 43

Fortran review questions

43.1 Fortran versus C++

Exercise 43.1. For each of C++, Fortran, Python:

• Give an example of an application or application area that the language is suited for, and
• Give an example of an application or application area that the language is not so suited for.

43.2 Basics

Exercise 43.2.

• What does the Parameter keyword do? Give an example where you would use it.
• Why would you use a Module?
• What is the use of the Intent keyword?

43.3 Arrays

Exercise 43.3. You are looking at historical temperature data, say a table of the high and low temperature at January 1st of every year between 1920 and now, so that is 100 years.

Your program accepts data as follows:

```fortran
Integer :: year, high, low
!! code omitted
read *, year, high, low
```

where the temperatures are rounded to the closest degree (Centigrade of Fahrenheit is up to you.)

Consider two scenarios. For both, give the lines of code for 1. the array in which you store the data, 2. the statement that inserts the values into the array.
43. Fortran review questions

- Store the raw temperature data.
- Suppose you are interested in knowing how often certain high/low temperatures occurred. For instance, 'how many years had a high temperature of 32F/0 C'.

43.4 Subprograms

Exercise 43.4. Write the missing procedure `pos_input` that
- reads a number from the user
- returns it
- and returns whether the number is positive
in such a way to make this code work:

```
program looppos
  implicit none
  real(4) :: userinput
  do while (pos_input(userinput))
    print '("Positive input:",f7.3)',&
    userinput
  end do
  print '("Nonpositive input:",f7.3)',&
  userinput
  !! ...
end program looppos
```

Output
[func] looppos:
Running with the following inputs:
5
1
-7.3
Positive input: 5.000
Positive input: 1.000
Nonpositive input: -7.300

Give the function parameter(s) the right `Intent` directive.

Hint: is `pos_input` a SUBROUTINE or FUNCTION? If the latter, what is the type of the function result? How many parameters does it have otherwise? Where does the variable `user_input` get its value? So what is the type of the parameter(s) of the function?
PART IV

JULIA (LARGELY YET TO BE WRITTEN)
Chapter 44

Basics of Julia

44.1 Statements

Each programming language has its own (very precise!) rules for what can go in a source file. Globally we can say that a program contains instructions for the computer to execute, and these instructions take the form of a bunch of ‘statements’. Here are some of the rules on statements; you will learn them in more detail as you go through this book.

**Program statements**

- A program contains statements. A simple statement is one that fits on one line. No need for a semicolon: the line end terminates it.
  \[ a = 1 \]

- You can multiple statements on one line by using semicolons:
  \[ a = 1; \ b = 2 \]

- Compound statements, such as conditionals, take up multiple lines:
  \[
  \text{if} \ a = 1 \\
  \quad \text{println}("It was one") \\
  \text{end}
  \]

- Comments are ‘Note to self’, short:
  \[ c = 3 \ # \text{set} \ c \text{ to three} \]

**Printing stuff**

The basics of interacting with a program are through the output statements `println` and `println`, and input `readline`.

\[
\begin{align*}
  a \ &= \ 1; \ b \ &= \ 2 \\
  \text{println}("a and b: ") \\
  \text{println}(a) \\
  \text{println}(" \ \") \\
  \text{println}(b)
\end{align*}
\]

or simpler:

\[
\text{println}("a and b: \$a \$b")
\]
44. Basics of Julia

44.2 Variables

A program could not do much without storing data: input data, temporary data for intermediate results, and final results. Data is stored in variables, which have

- a name, so that you can refer to them,
- a datatype, and
- a value.

Think of a variable as a labeled place in memory.

Variable names are more liberal than in other programming languages: many Unicode characters are allowed.

44.2.1 Datatypes

In Julia, like in Python, but unlike in C++, you do not need a variable declaration: a variable is created the first time you assign something to it, and its type is the type of the value you assign.

Variables have

- a name
- a type
- a value.

The type of the variable is determined by when a value is assigned to it. This is like Python, and unlike C.

Numerical types

The main numerical types are `Int64` and `Float64`, where the ‘64’ indicates that in both cases these are 64-bit types.

These are ‘concrete types’, but they are both based on the ‘abstract type’ `Real`, which is a supertype of both; see later.

Type of expression

Types can be determined by looking at the rhs expression, or explicitly forced:

<table>
<thead>
<tr>
<th>Code:</th>
<th>Output</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>one_int = 1</code></td>
<td><code>1 has type Int64</code></td>
</tr>
<tr>
<td><code>println(&quot;$one_int has type $(typeof(one_int))&quot;)</code></td>
<td><code>1 has type Int64</code></td>
</tr>
<tr>
<td><code>one_int = one(Int64)</code></td>
<td><code>1 has type Int64</code></td>
</tr>
<tr>
<td><code>println(&quot;$one_int has type $(typeof(one_int))&quot;)</code></td>
<td><code>1 has type Int64</code></td>
</tr>
<tr>
<td><code>one_float = 1.0</code></td>
<td><code>1.0 has type Float64</code></td>
</tr>
<tr>
<td><code>println(&quot;$one_float has type $(typeof(one_float))&quot;)</code></td>
<td><code>1.0 has type Float64</code></td>
</tr>
<tr>
<td><code>one_float = one(Float64)</code></td>
<td></td>
</tr>
<tr>
<td><code>println(&quot;$one_float has type $(typeof(one_float))&quot;)</code></td>
<td>}</td>
</tr>
</tbody>
</table>
44.2. Variables

Subtypes and supertypes

Types have a hierarchy.

The subtype relation is denoted with the <: relation:

\[
\text{Integer} <: \text{Number}
\]

This can also be used in functions:

\[
\text{function somecompute}(x \!: \text{T}) \text{ where } \text{T} <: \text{Real}
\]

44.2.1.1 Boolean values

Truth values

So far you have seen integer and real variables. There are also boolean values, type \text{Bool}, which represent truth values.

\[
\text{primitive type} \text{Bool} <: \text{Integer}\ \text{end}
\]

There are only two values: \text{true} and \text{false}.

\[
\text{bool found}\{\text{false}\}; \\
\text{found} = \text{true};
\]

To create an array of booleans you can

\[
\text{alltrue} = \text{trues}(n) \\
\text{allfalse} = \text{falses}(n)
\]

44.2.1.2 Characters and strings

Characters and strings

- Characters, of type \text{Char}, in single quotes
- Strings, of type \text{String}, in double quotes.

In addition to the regular 128 \text{ASCII} characters, \text{Unicode} characters can be entered through a backslash notation: \text{	extbackslash	extgamma}. This follows \text{LaTeX} naming conventions.

44.2.2 Truth values

In addition to numerical types, there are truth values, \text{true} and \text{false}, with all the usual logical operators defined on them.

Boolean expressions

- Testing: \text{==} \text{!=} \text{<} \text{>} \text{<=} \text{>=}
- Not, and, or: \text{!} \text{&&} \text{||}

Bool-int conversion

As in other languages, booleans can be implicitly interpreted as integer, with \text{true} corresponding to 1 and \text{false} to 0. However, conversion the other way is not as generous.

\[
1 + \text{true}
\]
Logical expressions in C++ are evaluated using shortcut operators: you can write

\[ x > 0 \land \sqrt{x} < 2 \]

If \( x \) is negative, the second part will never be evaluated because the ‘and’ conjunction can already be concluded to be false. Similarly, ‘or’ conjunctions will only be evaluated until the first true clause.

The ‘true’ and ‘false’ constants could strictly speaking be stored in a single bit. C++ does not do that, but there are bit operators that you can apply to, for instance, all the bits in an integer.

**Bit operators**

Bitwise: \& \mid \oplus

### 44.3 Expressions

Division \( 2/3 \) gives a \texttt{Float64} number. You can cast to integer:

\[ \texttt{half = Int64( (27+2)/2 )} \]

### 44.3.1 Terminal input

**Terminal input**

To make a program run dynamic, you can set starting values from keyboard input. For this, use \texttt{readline}, which takes keyboard input. To assign this input to a variable you need to parse that as the desired type, using the function \texttt{parse}.

\[ \texttt{n = parse(Int64, readline(stdin))} \]

### 44.4 Tuples

\( (a, b) = (1, 2) \)

even

\( (a, b) = (b, a) \)
Chapter 45

Conditionals

A program consisting of just a list of assignment and expressions would not be terribly versatile. At least you want to be able to say ‘if $x > 0$, do one computation, otherwise compute something else’, or ‘until some test is true, iterate the following computations’. The mechanism for testing and choosing an action accordingly is called a *conditional*.

45.1 Basic syntax

Conditionals are delimited by *if* and *end*.

```plaintext
if x<0
   x = 2*x; y = y/2;
else
   x = 3*x; y = y/3;
end
```

Chaining conditionals (where the dots stand for omitted code):

```plaintext
if x>0
   ....
elseif x<0
   ....
else
   ....
end
```

Nested conditionals:

```plaintext
if x>0
   if y>0
      ....
   else
      ....
   end
else
   ....
end
```

When you start nesting constructs, use indentation to make it clear which line is at which level. A good editor helps you with that.
Exercise 45.1. For what values of $x$ will the left code print ‘b’?

For what values of $x$ will the right code print ‘b’?

```
x = ## some float value
if x > 1
    println("a")
    if x > 2
        println("b")
    end
end
```

```
x = ## some float value
if x > 1
    println("a")
elseif x > 2
    println("b")
end
```

45.2 Advanced topics

45.2.1 Short-circuit operators

Julia logic operators have a feature called short-circuiting: a short-circuit operator stops evaluating when the result is clear. For instance, in

```
clause1 and clause2
```

the second clause is not evaluated if the first one is false, because the truth value of this conjunction is already determined.

Likewise, in

```
clause1 or clause2
```

the second clause is not evaluated if the first one is true.

This mechanism allows you to write

```
if ( x>=0 and sqrt(x)<10 ) { /* ... */ }
```

Without short-circuiting the square root operator could be applied to negative numbers.

45.2.2 Ternary if

The true and false branch of a conditional contain whole statements. For example

```
if (foo)
    x = 5;
else
    y = 6;
```

But what about the case where the true and false branch perform in effect the same action, and only differ by an expression?

```
if (foo)
    x = 5;
else
    x = 6;
```
For this case there is the ternary if, which acts as if it’s an expression itself, but chosen between two expressions. The previous assignment to \( x \) then becomes:

\[
x = \text{foo} ? 5 : 6;
\]

Surprisingly, this expression can even be in the left-hand side:

\[
\text{foo} ? x : y = 7;
\]
Chapter 46

Looping

See chapter 6 for a general introduction to loops.

46.1 Basics

Julia loops have a structure:

```julia
for var = some_range
    # statements
end

# or
for var in some_range
    # statements
end
```

Code:

```julia
function sum_of_cubes(n)
    cubesum = 0.
    for num in 1:n
        cubesum += num*num*num
    end
    return cubesum
end

n = 10
sumofcubes = sum_of_cubes(n)
println("Sum of $n cubes: $sumofcubes")
```

Output

[loopj] loop:
0
Sum of 10 squares: 385
Sum of 10 cubes: 3025.0

There is a subtlety using a loop at top level, for instance in the interpreter: not only the loop variable, but every scalar variable in the loop is then local. To access a variable from outside the loop you need to declare it `global`:
46. Looping

Code:
```plaintext
sum = 0; n = 10
println(sum)
for num in 1:n
    global sum
    sum += num*num
end
println("Sum of $n squares: $sum")
```

Output
[loop] loop:
0
Sum of 10 squares: 385
Sum of 10 cubes: 3025.0

Note that we said ‘scalar’ variable. This does not hold for array variable: those are always global.

46.1.1 Stride

Loops by default have a stride of 1. To use something else, write
```plaintext
for odd=1:2:10
    f(odd)
end
```
or
```plaintext
for down=10:-1:1
    f(down)
end
```

Exercise 46.1. Read an integer value with `cin`, and print ‘Hello world’ that many times.

Exercise 46.2. Extend exercise 6.2: the input 17 should now give lines
```
Hello world 1
Hello world 2
....
Hello world 17
```

Loops such as
```plaintext
for i in 1:10
```
have well-defined starting and ending values. However, loops can also iterate over more abstractly defined iteration spaces. You will see this later.

46.1.2 Nested loops

Quite often, the loop body will contain another loop. For instance, you may want to iterate over all elements in a matrix. Both loops will have their own unique loop variable.
This is called loop nest; the row-loop is called the outer loop and the column-loop the inner loop.

For a more compact syntax:

```plaintext
for i in 1:10, j in 1:10
  ...
end
```

This syntax makes it easier to break out of multiple loops.
46. Looping
Chapter 47

Functions

Read the introduction of chapter 7 for a general discussion of what functions are about.

Here is a single-line function definition:

```
Code:
```
double(x) = 2*x
println(double(6))
```

Output

```
[func] simpleone:
12
```

You may have noticed that this function definition does not include parameter or return types. Those are determined by the function invocation.

Technically, Julia uses *multiple dispatch* (which is known as *polymorphism* in other languages): the same function name can correspond to different computations, as long they differ in their *type signature*. Thus, a function such as `sin` can apply to both a scalar and matrix.

This (multiline) function prints out its argument type:

```
Code:
```
function verydouble(x)
    println("Arg type 
    2*x
end
println(verydouble(15))
println(verydouble(15.1))
println(verydouble([1,2]))
```

Output

```
[func] simplemulti:
Arg type Int64: 15
30
Arg type Float64: 15.1
30.2
Arg type Array{Int64,1}: [1, 2]
[2, 4]
```

You can enforce an argument type

```
myfunction( x::Float64 ) = #
```
47. Functions
Chapter 48

Arrays

48.1 Introduction

Create array of length 3, with values undefined.

```
Array{Int64}(undef, 3)
```

Create array with 2 rows and 3 columns, with values undefined.

```
Array{Integer}(undef, 2, 3)
```

Zero-based indexing:

```
mat = Array(Float64)(undef, 2, 4)
typeof(mat)
show(mat)
mat[1,3] = 3.14
show(mat)
```

Bound checking:

```
mat = Array(Float64)(undef, 2, 4)
mat[2,4] = 3.14
mat[0,0] = 1.1
show(mat)
```

48.1.1 Element access

Julia uses the square bracket notation

```
ar[5] = 6
```

with bounds that are 1-based.

(Fortran-style arbitrary lower bounds can be supported: https://docs.julialang.org/en/v1/devdocs/offset-arrays/)
48. Arrays

48.1.2 Arrays in linear algebra

The keywords `Vector` and `Matrix` are synonyms for

```
  Array{T,1}
  Array{T,2}
```

respectively.

Additionally, there are

- `Symmetric`: Symmetric matrix
- `Hermitian`: Hermitian matrix
- `UpperTriangular`: Upper triangular matrix
- `UnitUpperTriangular`: Upper triangular matrix with unit diagonal
- `LowerTriangular`: Lower triangular matrix
- `UnitLowerTriangular`: Lower triangular matrix with unit diagonal
- `UpperHessenberg`: Upper Hessenberg matrix
- `Tridiagonal`: Tridiagonal matrix
- `SymTridiagonal`: Symmetric tridiagonal matrix
- `Bidiagonal`: Upper/lower bidiagonal matrix
- `Diagonal`: Diagonal matrix
- `UniformScaling`: Uniform scaling operator

For some of these types, optimized addition and multiplication routines are available.

48.1.3 Type hierarchy

There is an untyped base type `AbstractMatrix` from which typed matrices are derived. You can use the function `eltype` to find out what the type of an abstract matrix is:

```
function look_at_matrix( A::AbstractMatrix )
  (size, type) = (size(A,1), eltype(A))
```

48.2 Functions

48.2.1 Built-in functions

`collect`: turn the elements of a collection or iterator into an array. Example:

```
  integers = collect( 1:n )
```

48.2.2 Scalar functions

Scalar functions such as `abs` can be applied in a pointwise manner to an array by using a dot-notation. Since this is ambiguous with taking a member of a structure, the array needs to be enclosed in parentheses:
48.3 Comprehensions

Code:

```julia
x = [2, 4, -6, 8, 1, -3, 5, 7, 9]
println("$x")
xmax = abs.(x)
println("$xmax")
```

Output

[arrayj] pointwise:

```text
[2, 4, -6, 8, 1, -3, 5, 7, 9]
[2, 4, 6, 8, 1, 3, 5, 7, 9]
```

48.2.3 Vectors are dynamic

An array can be grown or shrunk after its creation. For instance, you can use the `push!` method to add elements at the end:

**Dynamic vector extension**

Extend with `push!`:

Code:

```julia
foo = [1, 2, 3];
push!(foo, 4, 5, 6);
```

Output

[arrayj] push:

```
[1, 2, 3, 4, 5, 6]
```

48.3 Comprehensions

It is possible to define an array by its elements.

```
[i^2 for i in 1:10]
Complex[i^2 for i in 1:10]
[(i, sqrt(i)) for i in 1:10]
```

Two-dimensional:

```
[(r, c) for r in 1:5, c in 1:2]
```

With a test to filter:

```
[x for x in 1:100 if x % 7 == 0]
```

Enumerating:

```
[i for i in enumerate(m)]
```

3x3 Array(Tuple{Int64, Int64}, 2):

```
(1, 6)  (4, 5)  (7, 3)
(2, 4)  (5, 0)  (8, 7)
(3, 1)  (6, 7)  (9, 4)
```

Zip together multiple generators:

```
for i in zip(0:10, 100:110, 200:210)
    println(i)
end
```

```
(0,100,200)
(1,101,201)
```
You can iterators:

```
ro = 0:2:100
[i for i in ro]
```

### 48.4 Multi-dimensional cases

Julia has support for multi-dimensional arrays. Array types look like

```
Array{Int64,2}
```

for a two-dimensional array of \textit{Int64} objects.

**Array organization**

Arrays are organized by columns. For instance using `reshape` to make a two-dimensional array from one-dimensional one:

```
a = reshape(1:100, (10, 10))
for n in a
    print(n, " ")
end
```
Chapter 49

Structs

49.1 Why structures?

You have seen the basic datatypes in section 4.3.4. These are enough to program whatever you want, but it would be nice if the language had some datatypes that are more abstract, closer to the terms in which you think about your application. For instance, if you are programming something to do with geometry, you had rather talk about points than explicitly having to manipulate their coordinates.

Structures are a first way to define your own datatypes. A struct acts like a datatype for which you choose the name. A struct contains other datatypes; these can be elementary, or other structs.

```julia
mutable struct vector
    x::Float64
    y::Float64
    label::Int64
end
```

v1 = vector(1.,2.,5)
v2 = vector(3.,4.,6)
println("v2 has y=\$(v2.y)")
v2 = v1
println("v2 has y=\$(v2.y)")
```

The reason for using structures is to ‘raise the level of abstraction’: instead of talking about $x, y$-values, you can now talk about vectors and such. This makes your code look closer to the application you are modeling.

49.2 The basics of structures

A structure behaves like a data type: you declare variables of the structure type, and you use them in your program. The new aspect is that you first need to define the structure type. This definition can be done anywhere before you use it.

```julia
mutable struct vector
    x::Float64
    y::Float64
    label::Int64
end
```

377
49.3 Structures and functions

You can use structures with functions, just as you could with elementary datatypes. Julia here uses *multiple dispatch* (which is a form of polymorphism) where a function can receive additional definitions for operating on user-defined types.

49.3.1 Structures versus objects

Multiple dispatch on structures are Julia’s alternative to OOP! (OOP!): rather than having methods inside a defined class, functions are defined free-standing, operating on newly defined types.

While there is not much difference between `obj.method()` and `method(obj)`, things like inheritance are harder to realize.

**Exercise 49.1.** If you are doing the prime project (chapter 52) you can now do exercise 52.8.
Chapter 50

More Julia

50.1 Assertions

Test on dynamic conditions

function twice_root( x::T )
  @assert( x>0 )
  return 2*sqrt()
end
50. More Julia
PART V

EXERCISES AND PROJECTS
Chapter 51

Style guide for project submissions

The purpose of computing is insight, not numbers. (Richard Hamming)

Your project writeup is at least as important as the code. Here are some common-sense guidelines for a good writeup. However, not all parts may apply to your project. Use your good judgement.

**Style**  First of all, observe correct spelling and grammar. Use full sentences.

**Completeness**  Your writeup needs to have the same elements as a good paper:
- Title and author, including EID.
- A one-paragraph abstract.
- A bibliography at the end.

**Introduction**  The reader of your document need not be familiar with the project description, or even the problem it addresses. Indicate what the problem is, give theoretical background if appropriate, possibly sketch a historic background, and describe in global terms how you set out to solve the problem, as well as your findings.

**Code**  Your report should describe in a global manner the algorithms you developed, and you should include relevant code snippets. If you want to include full listings, relegate that to an appendix: code snippets should only be used to illustrate especially salient points.

Do not use screen shots of your code: at the very least use a `verbatim` environment, but using the `listings` package (used in this book) is very much recommended.

**Results and discussion**  Present tables and/or graphs when appropriate, but also include verbiage to explain what conclusions can be drawn from them.

You can also discuss possible extensions of your work to cases not covered.

**Summary**  Summarize your work and findings.
51. Style guide for project submissions
Chapter 52

Prime numbers

In this chapter you will do a number of exercises regarding prime numbers that build on each other. Each section lists the required prerequisites. Conversely, the exercises here are also referenced from the earlier chapters.

52.1 Arithmetic

*Before doing this section, make sure you study section 4.5.*

Exercise 52.1. Read two numbers and print out their modulus. Two ways:
- use the `cout` function to print the expression, or
- assign the expression to a variable, and print that variable.

52.2 Conditionals

*Before doing this section, make sure you study section 5.1.*

Exercise 52.2. Read two numbers and print a message stating whether the second is a divisor of the first:
52. Prime numbers

Code:
```cpp
int number, divisor;
bool is_a_divisor;
/* ... */
if (/* ... */) {
    cout << "Indeed, " << divisor
        << " is a divisor of "
        << number << endl;
} else {
    cout << "No, " << divisor
        << " is not a divisor of "
        << number << endl;
}
```

Output

[primes] division:
```
( echo 6 ; echo 2 ) | ldivisiontest
Enter a number:
Enter a trial divisor:
Indeed, 2 is a divisor of 6
```

```
( echo 9 ; echo 2 ) | ldivisiontest
Enter a number:
Enter a trial divisor:
No, 2 is not a divisor of 9
```

52.3 Looping

Before doing this section, make sure you study section 6.1.

Exercise 52.3. Read an integer and set a boolean variable to determine whether it is prime by testing for the smaller numbers if they divide that number.

Print a final message
```
Your number is prime
```
or
```
Your number is not prime: it is divisible by ....
```

where you report just one found factor.

Printing a message to the screen is hardly ever the point of a serious program. In the previous exercise, let’s therefore assume that the fact of primeness (or non-primeness) of a number will be used in the rest of the program. So you want to store this conclusion.

Exercise 52.4. Rewrite the previous exercise with a boolean variable to represent the primeness of the input number.

Exercise 52.5. Read in an integer $r$. If it is prime, print a message saying so. If it is not prime, find integers $p \leq q$ so that $r = p \cdot q$ and so that $p$ and $q$ are as close together as possible. For instance, for $r = 30$ you should print out $5, 6$, rather than $3, 10$. You are allowed to use the function $\text{sqrt}$. 

Introduction to Scientific Programming
52.4 Functions

Before doing this section, make sure you study section 7.

Above you wrote several lines of code to test whether a number was prime.

Exercise 52.6. Write a function `test_if_prime` that has an integer parameter, and returns a boolean corresponding to whether the parameter was prime.

```cpp
int main() {
    bool isprime;
    isprime = test_if_prime(13);
}
```

Read the number in, and print the value of the boolean.

Does your function have one or two `return` statements? Can you imagine what the other possibility looks like? Do you have an argument for or against it?

52.5 While loops

Before doing this section, make sure you study section 6.2.

Exercise 52.7. Take your prime number testing function `test_if_prime`, and use it to write a program that prints multiple primes:

- Read an integer `how_many` from the input, indicating how many (successive) prime numbers should be printed.
- Print that many successive primes, each on a separate line.
- (Hint: keep a variable `number_of_primes_found` that is increased whenever a new prime is found.)

52.6 Structures

Before doing this section, make sure you study section 9.1, 15.1.

A `struct` functions to bundle together a number of data item. We only discuss this as a preliminary to classes.

Exercise 52.8. Rewrite the exercise that found a predetermined number of primes, putting the `number_of_primes_found` and `last_number_tested` variables in a structure. Your main program should now look like:

```cpp
cin >> nprimes;
struct primesequence sequence;
while (sequence.number_of_primes_found<nprimes) {
    int number = nextprime(sequence);
    cout << "Number " << number << " is prime" << endl;
}
```
52. Prime numbers

Hint: the variable last_number_tested does not appear in the main program. Where does it get updated? Also, there is no update of number_of_primes_found in the main program. Where do you think it would happen?

52.7 Classes and objects

Before doing this section, make sure you study section 10.1.

In exercise 52.8 you made a structure that contains the data for a primesequence, and you have separate functions that operate on that structure or on its members.

Exercise 52.9. Write a class primegenerator that contains

- members how_many_primes_found and last_number_tested,
- a method nextprime;
- Also write a function isprime that does not need to be in the class.

Your main program should look as follows:

```cpp
    cin >> nprimes;
    primegenerator sequence;
    while (sequence.number_of_primes_found()<nprimes) {
        int number = sequence.nextprime();
        cout << "Number " << number << " is prime" << endl;
    }
```

In the previous exercise you defined the primegenerator class, and you made one object of that class:

```cpp
    primegenerator sequence;
```

But you can make multiple generators, that all have their own internal data and are therefore independent of each other.

Exercise 52.10. The Goldbach conjecture says that every even number, from 4 on, is the sum of two primes \( p + q \). Write a program to test this for the even numbers up to a bound that you read in. Use the primegenerator class you developed in exercise 52.9.

This is a great exercise for a top-down approach!

1. Make an outer loop over the even numbers \( e \).
2. For each \( e \), generate all primes \( p \).
3. From \( p + q = e \), it follows that \( q = e - p \) is prime: test if that \( q \) is prime.

For each even number \( e \) then print \( e, p, q \), for instance:

```
The number 10 is 3+7
```

If multiple possibilities exist, only print the first one you find.
Exercise 52.11. The Goldbach conjecture says that every even number \(2n\) (starting at 4), is the sum of two primes \(p + q\):

\[
2n = p + q.
\]

Equivalently, every number \(n\) is equidistant from two primes:

\[
n = \frac{p + q}{2} \quad \text{or} \quad q - n = n - p.
\]

In particular this holds for each prime number:

\[
\forall_r \exists_{p,q \text{ prime}}: r = (p + q)/2 \text{ is prime}.
\]

Write a program that tests this. You need at least one loop that tests all primes \(r\); for each \(r\) you then need to find the primes \(p, q\) that are equidistant to it. Do you use two generators for this, or is one enough?

For each \(r\) value, when the program finds the \(p, q\) values, print the \(q, p, r\) triple and move on to the next \(r\).

Allocate an array where you record all the \(p - q\) distances that you found. Print some elementary statistics, for instance: what is the average, do the distances increase or decrease with \(p\)?

---

52.7.1 Exceptions

Before doing this section, make sure you study section 23.2.2.

Exercise 52.12. Revisit the prime generator class (exercise 52.9) and let it throw an exception once the candidate number is too large. (You can hardwire this maximum, or use a limit; section 24.6.)

**Code:**

```cpp
try {
    do {
        auto cur = primes.nextprime();
        cout << cur << endl;
    } while (true);
} catch (string s) {
    cout << s << endl;
}
```

**Output**

```
[primes] genx:
9931
9941
9949
9967
9973
Reached max int
```

52.7.2 Prime number decomposition

Before doing this section, make sure you study section 24.2.1.

Design a class \texttt{Integer} which stores its value as its prime number decomposition. For instance,

\[
180 = 2^2 \cdot 3^2 \cdot 5 \quad \Rightarrow \quad [2:2, 3:2, 5:1]
\]
You can implement this decomposition itself as a vector, (the $i$-th location stores the exponent of the $i$-th prime) but let’s use a map instead.

**Exercise 52.13.** Write a constructor of an Integer from an int, and methods `as_int / as_string` that convert the decomposition back to something classical. Start by assuming that each prime factor appears only once.

**Code:**

```cpp
Integer i2(2);
cout << i2.as_string() << " : " << i2.as_int() << endl;

Integer i6(6);
cout << i6.as_string() << " : " << i6.as_int() << endl;
```

**Output**

```
[primes] decomposition26:
```

**Exercise 52.14.** Extend the previous exercise to having multiplicity $> 1$ for the prime factors.

**Code:**

```cpp
Integer i180(180);
cout << i180.as_string() << " : " << i180.as_int() << endl;
```

**Output**

```
[primes] decomposition180:
2^2 3^2 5^1 : 180
```

Implement addition and multiplication for Integers.

Implement a class `Rational` for rational numbers, which are implemented as two `Integer` objects. This class should have methods for addition and multiplication. Write these through operator overloading if you’ve learned this.

Make sure you always divide out common factors in the numerator and denominator.

### 52.8 Other

The following exercise requires `std::optional`, which you can learn about in section 24.5.2.

**Exercise 52.15.** Write a function `first_factor` that optionally returns the smallest factor of a given input.

```cpp
auto factor = first_factor(number);
if (factor.has_value())
    cout << "Found factor: " << factor.value() << endl;
//answersnippet optfactortest
/* ... */
else
    cout << "Prime number\n";
```
52.9 Eratosthenes sieve

The Eratosthenes sieve is an algorithm for prime numbers that step-by-step filters out the multiples of any prime it finds.

1. Start with the integers from 2: 2, 3, 4, 5, 6, . . .
2. The first number, 2, is a prime: record it and remove all multiples, giving 3, 5, 7, 9, 11, 13, 15, 17 . . .
3. The first remaining number, 3, is a prime: record it and remove all multiples, giving 5, 7, 11, 13, 17, 19, 23, 25, 29 . . .
4. The first remaining number, 5, is a prime: record it and remove all multiples, giving 7, 11, 13, 17, 19, 23, 29, . . .

52.9.1 Arrays implementation

The sieve can be implemented with an array that stores all integers.

Exercise 52.16. Read in an integer that denotes the largest number you want to test. Make an array of integers that long. Set the elements to the successive integers. Apply the sieve algorithm to find the prime numbers.

52.9.2 Streams implementation

The disadvantage of using an array is that we need to allocate an array. What’s more, the size is determined by how many integers we are going to test, not how many prime numbers we want to generate. We are going to take the idea above of having a generator object, and apply that to the sieve algorithm: we will now have multiple generator objects, each taking the previous as input and erasing certain multiples from it.

Exercise 52.17. Write a stream class that generates integers and use it through a pointer.
Next, we need a stream that takes another stream as input, and filters out values from it.

Exercise 52.18. Write a class `filtered_stream` with a constructor

\[
\text{filtered_stream}(\text{int filter, shared_ptr<stream> input});
\]

that

1. Implements `next`, giving filtered values,
2. by calling the `next` method of the input stream and filtering out values.

Code:

```cpp
auto integers = make_shared<stream>();
auto odds = shared_ptr<stream> (new filtered_stream(2, integers));
for (int step=0; step<5; step++)
    cout << "next odd: " << odds->next() << endl;
```

Output

[sieve] odds:
next odd: 3
next odd: 5
next odd: 7
next odd: 9
next odd: 11

Now you can implement the Eratosthenes sieve by making a `filtered_stream` for each prime number.

Exercise 52.19. Write a program that generates prime numbers as follows.

- Maintain a `current` stream, that is initially the stream of prime numbers.
- Repeatedly:
  - Record the first item from the current stream, which is a new prime number;
  - and set `current` to a new stream that takes `current` as input, filtering out multiples of the prime number just found.

52.10 Range implementation

*Before doing this section, make sure you study section 26.2.*
Exercise 52.20. Make a \texttt{primes} class that can be ranged:

\begin{verbatim}
primegenerator allprimes;
for ( auto p : allprimes ) {
    cout << p << ", ";
    if (p>100) break;
}
cout << endl;
\end{verbatim}

Output
\texttt{[primes] range:}
\texttt{2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97, 101, 103, 107, 109, 113, ...

Victor Eijkhout
52. Prime numbers
Chapter 53

Geometry

In this set of exercises you will write a small ‘geometry’ package: code that manipulates points, lines, shapes. These exercises mostly use the material of section 10.

53.1 Basic functions

Exercise 53.1. Write a function with (float or double) inputs \( x, y \) that returns the distance of point \((x, y)\) to the origin.

Test the following pairs: 1, 0; 0, 1; 1, 1; 3, 4.

Exercise 53.2. Write a function with inputs \( x, y, \theta \) that alters \( x \) and \( y \) corresponding to rotating the point \((x, y)\) over an angle \( \theta \).

\[
\begin{pmatrix} x' \\ y' \end{pmatrix} = \begin{pmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{pmatrix} \begin{pmatrix} x \\ y \end{pmatrix}
\]

Your code should behave like:

```
code:
const float pi = 2*acos(0.0);
float x(1.), y(0.);
rotate(x, y, pi/4);
cout << "Rotated halfway: (" << x << "," << y << ")" << endl;
rotate(x, y, pi/4);
cout << "Rotated to the y-axis: (" << x << "," << y << ")" << endl;
```

Output
[geom] rotate:
Rotated halfway: (0.707107,0.707107)
Rotated to the y-axis: (0,1)
53.2 Point class

Before doing this section, make sure you study section 10.1.

A class can contain elementary data. In this section you will make a Point class that models cartesian coordinates and functions defined on coordinates.

Exercise 53.3. Make class Point with a constructor

\[
\text{Point}( \text{float} \ x\text{coordinate}, \text{float} \ y\text{coordinate});
\]

Write the following methods:

- distance_to_origin returns a float.
- printout uses cout to display the point.
- angle computes the angle of vector (x, y) with the x-axis.

Exercise 53.4. Extend the Point class of the previous exercise with a method: distance that computes the distance between this point and another: if p, q are Point objects,

\[
p\text{.distance}(q)
\]

computes the distance between them.

Hint: remember the ‘dot’ notation for members.

Exercise 53.5. Write a method halfway_point that, given two Point objects p, q, construct the Point halfway, that is, \((p + q)/2\):

```cpp
Point p(1,2.2), q(3.4,5.6);
Point h = p.halfway(q);
```

You can write this function directly, or you could write functions Add and Scale and combine these. (Later you will learn about operator overloading.)

How would you print out a Point to make sure you compute the halfway point correctly?

Exercise 53.6. Make a default constructor for the point class:

\[
\text{Point}() \{ \text{/\* default code */} \}
\]

which you can use as:

\[
\text{Point} \ p;
\]

but which gives an indication that it is undefined:
53.3 Using one class in another

Before doing this section, make sure you study section 10.2.

Exercise 53.9. Make a class LinearFunction with a constructor:

```cpp
LinearFunction(Point input_p1, Point input_p2);
```
and a member function

```cpp
float evaluate_at(float x);
```
which you can use as:

```cpp
LinearFunction line(p1, p2);
cout << "Value at 4.0: " << line.evaluate_at(4.0) << endl;
```

Exercise 53.10. Make a class LinearFunction with two constructors:

```cpp
LinearFunction(Point input_p2);
LinearFunction(Point input_p1, Point input_p2);
```
where the first stands for a line through the origin.
Implement again the evaluate function so that
Suppose you want to write a Rectangle class, which could have methods such as `float Rectangle::area()` or `bool Rectangle::contains(Point)`. Since rectangle has four corners, you could store four Point objects in each Rectangle object. However, there is redundancy there: you only need three points to infer the fourth. Let’s consider the case of a rectangle with sides that are horizontal and vertical; then you need only two points.

Axi-parallel rectangle class

Intended API:

```cpp
float Rectangle::area();
```

It would be convenient to store width and height; for

```cpp
bool Rectangle::contains(Point);
```

it would be convenient to store bottomleft/topright points.

Exercise 53.12.

1. Make a class `Rectangle` (sides parallel to axes) with a constructor:

```cpp
Rectangle(Point bl, float w, float h);
```

The logical implementation is to store these quantities. Implement methods

```cpp
float area(); float rightedge(); float topedge();
```

and write a main program to test these.

2. Add a second constructor

```cpp
Rectangle(Point bl, Point tr);
```

Can you figure out how to use member initializer lists for the constructors?

3. Make a copy of your file, and redesign your class so that it stores two Point objects. Your main program should not change.

The previous exercise illustrates an important point: for well designed classes you can change the implementation (for instance motivated by efficiency) while the program that uses the class does not change.
53.4 Is-a relationship

Before doing this section, make sure you study section 10.3.

Exercise 53.13. Take your code where a Rectangle was defined from one point, width, and height. Make a class Square that inherits from Rectangle. It should have the function area defined, inherited from Rectangle.

First ask yourself: what should the constructor of a Square look like?

Now generalize LinearFunction to StraightLine class. These two are almost the same except for vertical lines. The slope and intercept do not apply to vertical lines, so design StraightLine so that it stores the defining points internally. Let LinearFunction inherit.

53.5 More stuff

Before doing this section, make sure you study section 15.3.

The Rectangle class stores at most one corner, but may be convenient to sometimes have an array of all four corners.

Exercise 53.15. Add a method

```cpp
||const vector<Point> &corners()```

to the Rectangle class. The result is an array of all four corners, not in any order. Show by a compiler error that the array can not be altered.
53. Geometry
Chapter 54

Infectious disease simulation

This section contains a sequence of exercises that builds up to a somewhat realistic simulation of the spread of infectious diseases.

54.1 Model design

It is possible to model disease propagation statistically, but here we will build an explicit simulation: we will maintain an explicit description of all the people in the population, and track for each of them their status.

We will use a simple model where a person can be:

- sick: when they are sick, they can infect other people;
- susceptible: they are healthy, but can be infected;
- recovered: they have been sick, but no longer carry the disease, and can not be infected for a second time;
- vaccinated: they are healthy, do not carry the disease, and can not be infected.

In more complicated models a person could be infectious during only part of their illness, or there could be secondary infections with other diseases, et cetera. We keep it simple here: any sick person is can infect others while they are sick.

In the exercises below we will gradually develop a somewhat realistic model of how the disease spreads from an infectious person. We always start with just one person infected. The program will then track the population from day to day, running indefinitely until none of the population is sick. Since there is no re-infection, the run will always end.

54.1.1 Other ways of modeling

Instead of capturing every single person in code, a ‘contact network’ model, it is possible to use an ODE approach to disease modeling. You would then model the percentage of infected persons by a single scalar, and derive relations for that and other scalars [2].

This is known as a ‘compartmental model’, where each of the three SIR states is a compartment: a section of the population. Both the contact network and the compartmental model capture part of the truth.
fact, they can be combined. We can consider a country as a set of cities, where people travel between any pair of cities. We then use a compartmental model inside a city, and a contact network between cities. In this project we will only use the network model.

54.2 Coding

54.2.1 The basics

We start by writing code that models a single person. The main methods serve to infect a person, and to track their state. We need to have some methods for inspecting that state.

The intended output looks something like:

On day 10, Joe is susceptible
On day 11, Joe is susceptible
On day 12, Joe is susceptible
On day 13, Joe is susceptible
On day 14, Joe is sick (5 to go)
On day 15, Joe is sick (4 to go)
On day 16, Joe is sick (3 to go)
On day 17, Joe is sick (2 to go)
On day 18, Joe is sick (1 to go)
On day 19, Joe is recovered

Exercise 54.1. Write a Person class with methods:

- status_string() : returns a description of the person’s state as a string;
- update() : update the person’s status to the next day;
- infect(n) : infect a person, with the disease to run for n days;
- is_stable() : return a bool indicating whether the person has been sick and is recovered.

Your main program could for instance look like:

```cpp
Person joe;
int step = 1;
for ( ; ; step++) {
    joe.update();
    float bad_luck = (float) rand()/(float) RAND_MAX;
    if (bad_luck>.95)
        joe.infect(5);
    cout << "On day " << step << " , Joe is " << joe.status_string() << endl;
    if (joe.is_stable())
        break;
}
```
Here is a suggestion how you can model disease status. Use a single integer with the following interpretation:

- healthy but not vaccinated, value 0,
- recovered, value −1,
- vaccinated, value −2,
- and sick, with \( n \) days to go before recovery, modeled by value \( n \).

The `Person::update` method then updates this integer.

**Remark 17** Consider a point of programming style. Now that you’ve modeled the state of a person with an integer, you can use that as

```c
void infect(n) {
  if (state==0)
    state = n;
}
```

But you can also write

```c
bool is_susceptible() {
  return state==0;
}
void infect(n) {
  if (is_susceptible())
    state = n;
}
```

Which do you prefer and why?

### 54.2.2 Population

Next we need a `Population` class. Implement a population as a vector consisting of `Person` objects. Initially we only infect one person, and there is no transmission of the disease.

The trace output should look something like:

```
Size of population?
Disease ran its course by step 6
```

**Remark 18** Such a display is good for a sanity check on your program behavior. If you include such displays in your writeup, make sure to use a monospace font, and don’t use a population size that needs line wrapping. In further testing, you should use large populations, but do not include these displays.
Exercise 54.2. Program a population without infection.

- Write the `Population` class. The constructor takes the number of people:
  \[
  \text{Population population(npeople)};
  \]
- Write a method that infects a random person:
  \[
  \text{population.random_infection();}
  \]
  For the ‘random’ part you can use the C language random number generator (section 7.8.1), or the new STL one in section 24.8.
- Write a method `count_infected` that counts how many people are infected.
- Write an `update` method that updates all persons in the population.
- Loop the `update` method until no people are infected: the `Population::update` method should apply `Person::update` to all person in the population.

Write a routine that displays the state of the popular, using for instance: ? for susceptible, + for infected, – for recovered.

54.2.3 Contagion

This past exercise was too simplistic: the original patient zero was the only one who ever got sick. Now let’s incorporate contagion, and investigate the spread of the disease from a single infected person.

We start with a very simple model of infection.

Exercise 54.3. Read in a number \(0 \leq p \leq 1\) representing the probability of disease transmission upon contact.

\[
\text{population.set_probability_of_transfer(probability)};
\]

Incorporate this into the program: in each step the direct neighbours of an infected person can now get sick themselves. Run a number of simulations with population sizes and contagion probabilities. Are there cases where people escape getting sick?

Exercise 54.4. Incorporate vaccination: read another number representing the percentage of people that has been vaccinated. Choose those members of the population randomly.

Describe the effect of vaccinated people on the spread of the disease. Why is this model unrealistic?

54.2.4 Spreading

To make the simulation more realistic, we let every sick person come into contact with a fixed number of random people every day. This gives us more or less the `SIR model`; https://en.wikipedia.org/wiki/Epidemic_model.

Set the number of people that a person comes into contact with, per day, to 6 or so. (You can also let this be an upper bound for a random value, but that does not essentially change the simulation.) You have
already programmed the probability that a person who comes in contact with an infected person gets sick themselves. Again start the simulation with a single infected person.

Exercise 54.5. Code the random interactions. Now run a number of simulations varying
- The percentage of people vaccinated, and
- the chance the disease is transmitted on contact.

Record how long the disease runs through the population. With a fixed number of contacts and probability of transmission, how is this number of function of the percentage that is vaccinated?

Report this function as a table or graph. Make sure you have enough data points for a meaningful conclusion. Use a realistic population size. You can also do multiple runs and report the average, to even out the effect of the random number generator.

Exercise 54.6. Investigate the matter of ‘herd immunity’: if enough people are vaccinated, then some people who are not vaccinated will still never get sick. Let’s say you want to have this probability over 95 percent. Investigate the percentage of vaccination that is needed for this as a function of the contagiousness of the disease.

As in the previous exercise, make sure your data set is large enough.

54.2.5 Diseases without vaccine: Ebola and Covid-19

This section is optional, for bonus points

The project so far applies to diseases for which a vaccine is available, such as MMR for measles, mumps and rubella. The analysis becomes different if no vaccine exists, such as is the case for ebola and covid-19, as of this writing.

Instead, you need to incorporate ‘social distancing’ into your code: people do not get in touch with random others anymore, but only those in a very limited social circle. Design a model distance function, and explore various settings.

The difference between ebola and covid-19 is how long an infection can go unnoticed: the incubation period. With ebola, infection is almost immediately apparent, so such people are removed from the general population and treated in a hospital. For covid-19, a person can be infected, and infect others, for a number of days before they are sequestered from the population.

Add this parameter to your simulation and explore the behavior of the disease as a function of it.

54.3 Ethics

The subject of infectious diseases and vaccination is full of ethical questions. The main one is The chances of something happening to me are very small, so why shouldn’t I bend the rules a little?. This reasoning is most often applied to vaccination, where people for some reason or other refuse to get vaccinated.
Explore this question and others you may come up with: it is clear that everyone bending the rules will have disastrous consequences, but what if only a few people did this?

54.4 Project writeup and submission

54.4.1 Program files

In the course of this project you have written more than one main program, but some code is shared between the multiple programs. Organize your code with one file for each main program, and a single ‘library’ file with the class methods.

You can do this two ways:

1. You make a ‘library’ file, say infect_lib.cc, and your main programs each have a line
   
   ```
   #include "infect_lib.cc"
   ```

   This is not the best solution, but it is acceptable for now.

2. The better solution requires you to use separate compilation for building the program, and you need a header file. You would now have infect_lib.cc which is compiled separately, and infect_lib.h which is included both in the library file and the main program:

   ```
   #include "infect_lib.h"
   ```

   See section 19.1.2 for more information.

Submit all source files with instructions on how to build all the main programs. You can put these instructions in a file with a descriptive name such as README or INSTALL, or you can use a makefile.

54.4.2 Writeup

In the writeup, describe the ‘experiments’ you have performed and the conclusions you draw from them. The exercises above give you a number of questions to address.

For each main program, include some sample output, but note that this is no substitute for writing out your conclusions in full sentences.

The exercises in section 54.2.4 ask you to explore the program behavior as a function of one or more parameters. Include a table to report on the behavior you found. You can use Matlab or Matplotlib in Python (or even Excell) to plot your data, but that is not required.

54.5 Bonus: mathematical analysis

The SIR model can also be modeled through coupled difference or differential equations.

1. The number $S_i$ of susceptible people at time $i$ decreases by a fraction

   $$S_{i+1} = S_i (1 - \lambda_i \, dt)$$

   where $\lambda_i$ is the product of the number of infected people and a constant that reflects the number of meetings and the infectiousness of the disease. We write:

   $$S_{i+1} = S_i (1 - \lambda I_i \, dt)$$
2. The number of infected people similarly increases by $\lambda S_i I_i$, but it also decreases by people recovering (or dying):

$$I_{i+1} = I_i (1 + \lambda S_i \, dt - \gamma \, dt).$$

3. Finally, the number of ‘removed’ people equals that last term:

$$R_{i+1} = R_i (1 + \gamma I_i).$$

Exercise 54.7. Code this scheme. What is the effect of varying $dt$?

Exercise 54.8. For the disease to become an epidemic, the number of newly infected has to be larger than the number of recovered. That is,

$$\lambda S_i I_i - \gamma I_i > 0 \iff S_i > \gamma / \lambda.$$  

Can you observe this in your simulations?

The parameter $\gamma$ has a simple interpretation. Suppose that a person stays ill for $\delta$ days before recovering. If $I_t$ is relatively stable, that means every day the same number of people get infected as recover, and therefore a $1/\delta$ fraction of people recover each day. Thus, $\gamma$ is the reciprocal of the duration of the infection in a given person.
54. Infectious disease simulation
Chapter 55

Google PageRank

55.1 Basic ideas

We are going to simulate the Internet. In particular, we are going to simulate the Pagerank algorithm by which Google determines the importance of web pages.

Let’s start with some basic classes:

• A Page contains some information such as its title and a global numbering in Google’s data-center. It also contains a collection of links.

• We represent a link with a pointer to a Page. Conceivably we could have a Link class, containing further information such as probability of being clicked, or number of times clicked, but for now a pointer will do.

• Ultimately we want to have a class Web which contains a number of pages and their links. The web object will ultimately also contain information such as relative importance of the pages.

This application is a natural one for using pointers. When you click on a link on a web page you go from looking at one page in your browser to looking at another. You could implement this by having a pointer to a page, and clicking updates the value of this pointer.

Exercise 55.1. Make a class Page which initially just contains the name of the page. Write a method to display the page. Since we will be using pointers quite a bit, let this be the intended code for testing:

```cpp
auto homepage = make_shared<Page>("My Home Page");
cout << "Homepage has no links yet:" << endl;
cout << homepage->as_string() << endl;
```

Next, add links to the page. A link is a pointer to another page, and since there can be any number of them, you will need a vector of them. Write a method click that follows the link. Intended code:

```cpp
auto utexas = make_shared<Page>("University Home Page");
homepage->add_link(utexas);
auto searchpage = make_shared<Page>("google");
homepage->add_link(searchpage);
cout << homepage->as_string() << endl;
```
Exercise 55.2. Add some more links to your homepage. Write a method `random_click` for the `Page` class. Intended code:

```cpp
for (int iclick=0; iclick<20; iclick++) {
    auto newpage = homepage->random_click();
    cout << "To: " << newpage->as_string() << endl;
}
```

How do you handle the case of a page without links?

55.2 Clicking around

Exercise 55.3. Now make a class `Web` which foremost contains a bunch (technically: a vector) of pages. Or rather: of pointers to pages. Since we don’t want to build a whole internet by hand, let’s have a method `create_random_links` which makes a random number of links to random pages. Intended code:

```cpp
Web internet(netsize);
internet.create_random_links(avglinks);
```

Now we can start our simulation. Write a method `Web::random_walk` that takes a page, and the length of the walk, and simulates the result of randomly clicking that many times on the current page. (Current page. Not the starting page.)

Let’s start working towards PageRank. First we see if there are pages that are more popular than others. You can do that by starting a random walk once on each page. Or maybe a couple of times.

Exercise 55.4. Apart from the size of your internet, what other design parameters are there for your tests? Can you give a back-of-the-envelope estimation of their effect?

Exercise 55.5. Your first simulation is to start on each page a number of times, and counts where that lands you. Intended code:

```cpp
vector<int> landing_counts(internet.number_of_pages(),0);
for ( auto page : internet.all_pages() ) {
    for (int iwalk=0; iwalk<5; iwalk++) {
        auto endpage = internet.random_walk(page,2*avglinks,tracing);
        landing_counts.at(endpage->global_ID())++;
    }
}
```

Display the results and analyze. You may find that you finish on certain pages too many times. What’s happening? Fix that.
55.3 Graph algorithms

There are many algorithms that rely on gradually traversing the web. For instance, any graph can be connected. You test that by

- Take an arbitrary vertex $v$. Make a ‘reachable set’ $R \leftarrow \{v\}$.
- Now see where you can get from your reachable set:
  \[ \forall v \in V \forall w \text{ neighbour of } v : R \leftarrow R \cup \{w\} \]
- Repeat the previous step until $R$ does not change anymore.

After this algorithm concludes, is $R$ equal to your set of vertices? If so, your graph is called (fully) connected. If not, your graph has multiple connected components.

Exercise 55.6. Code the above algorithm, keeping track of how many steps it takes to reach each vertex $w$. This is the Single Source Shortest Path algorithm (for unweighted graphs).

The diameter is defined as the maximal shortest path. Code this.

55.4 Page ranking

The Pagerank algorithm now asks, if you keep clicking randomly, what is the distribution of how likely you are to wind up on a certain page. The way we calculate that is with a probability distribution: we assign a probability to each page so that the sum of all probabilities is one. We start with a random distribution:

```cpp
ProbabilityDistribution
    random_state(internet.number_of_pages());
    random_state.set_random();
    cout << "Initial distribution: " << random_state.as_string() << endl;
```

Exercise 55.7. Implement a class `ProbabilityDistribution`, which stores a vector of floating point numbers. Write methods for:

- accessing a specific element,
- setting the whole distribution to random, and
- normalizing so that the sum of the probabilities is 1.
- a method rendering the distribution as string could be useful too.

Next we need a method that given a probability distribution, gives you the new distribution corresponding to performing a single click.
Exercise 55.8. Write the method

\[
\text{ProbabilityDistribution Web::globalclick ( ProbabilityDistribution currentstate );}
\]

Test it by
- start with a distribution that is nonzero in exactly one page;
- print the new distribution corresponding to one click;
- do this for several pages and inspect the result visually.

Then start with a random distribution and run a couple of iterations. How fast does the process converge? Compare the result to the random walk exercise above.

Exercise 55.9. In the random walk exercise you had to deal with the fact that some pages have no outgoing links. In that case you transitioned to a random page. That mechanism is lacking in the \text{globalclick} method. Figure out a way to incorporate this.

Let’s simulate some simple ‘search engine optimization’ trick.

Exercise 55.10. Add a page that you will artificially made look important: add a number of pages (for instance four times the average number of links) that all link to this page, but no one links to them. (Because of the random clicking they will still sometimes be reached.)

Compute the rank of the artificially hyped page. Did you manage to trick Google into ranking this page high?

55.5 Graphs and linear algebra

The probability distribution is essentially a vector. You can also represent the web as a matrix \( W \) with \( w_{ij} = 1 \) if page \( i \) links to page \( j \). How can you interpret the \text{globalclick} method in these terms?

Exercise 55.11. Add the matrix representation of the \text{Web} object and reimplement the \text{globalclick} method. Test for correctness.

Do a timing comparison.

The iteration you did above to find a stable probability distribution corresponds to the ‘power method’ in linear algebra. Look up the Perron-Frobenius theory and see what it implies for page ranking.
Chapter 56

Redistricting

In this project you can explore ‘gerrymandering’, the strategic drawing of districts to give a minority population a majority of districts\(^1\).

56.1 Basic concepts

We are dealing with the following concepts:

- A state is divided into census districts, which are given. Based on census data (income, ethnicity, median age) one can usually make a good guess as to the overall voting in such a district.
- There is a predetermined number of congressional districts, each of which consists of census districts. A congressional district is not a random collection: the census districts have to be contiguous.
- Every couple of years, to account for changing populations, the district boundaries are redrawn. This is known as redistricting.

There is considerable freedom in how redistricting is done: by shifting the boundaries of the (congressional) districts it is possible to give a population that is in the overall minority a majority of districts. This is known as gerrymandering.

For background reading, see https://redistrictingonline.org/.

To do a small-scale computer simulation of gerrymandering, we make some simplifying assumption.

- First of all, we dispense with census district: we assume that a district consists directly of voters, and that we know their affiliation. In practice one relies on proxy measures (such as income and education level) to predict affiliation.
- Next, we assume a one-dimensional state. This is enough to construct examples that bring out the essence of the problem:
  
  Consider a state of five voters, and we designate their votes as AAABB. Assigning them to three (contiguous) districts can be done as AAA | B | B, which has one ‘A’ district and two ‘B’ districts.

- We also allow districts to be any positive size, as long as the number of districts is fixed.

\(^{1}\) This project is obviously based on the Northern American political system. Hopefully the explanations here are clear enough. Please contact the author if you know of other countries that have a similar system.
56. Redistricting

56.2 Basic functions

56.2.1 Voters

We dispense with census districts, expressing everything in terms of voters, for which we assume a known voting behaviour. Hence, we need a **Voter** class, which will record the voter ID and party affiliation. We assume two parties, and leave an option for being undecided.

**Exercise 56.1.** Implement a **Voter** class. You could for instance let ±1 stand for A/B, and 0 for undecided.

```cpp
// Code:
cout << "Voter 5 is positive:" << endl;
Voter nr5(5,+1);
cout << nr5.print() << endl;
/* ... */
cout << "Voter 6 is negative:" << endl;
Voter nr6(6,-1);
cout << nr6.print() << endl;
/* ... */
cout << "Voter 7 is weird:" << endl;
Voter nr7(7,3);
cout << nr7.print() << endl;
```

**Output**

```
[gerry] voters:
Voter 5 is positive: 5:+
Voter 6 is negative: 6:-
Voter 7 is weird: Illegal affiliation value: 3
Error in creating voter 7
```

missing snippet voterneg  missing snippet voterwrong

56.2.2 Populations

**Exercise 56.2.** Implement a **District** class that models a group of voters.

- You probably want to create a district out of a single voter, or a vector of them. Having a constructor that accepts a string representation would be nice too.
- Write methods **majority** to give the exact majority or minority, and **lean** that evaluates whether the district overall counts as A part or B party.
- Write a **sub** method to creates subsets.
  ```cpp
  District District::sub(int first, int last);
  ```
- For debugging and reporting it may be a good idea to have a method
  ```cpp
  string District::print();
  ```
56.2. Basic functions

**Code:**

```cpp
cout << "Making district with one B voter";
Voter nr5(5,+1);
District nine( nr5 );
cout << ".. size: " << nine.size() << endl;
cout << ".. lean: " << nine.lean() << endl;
/* ... */
cout << "Making district ABA" << endl;
District nine( vector<Voter> 
{ {1,-1},{2,+1},{3,-1} } );
cout << ".. size: " << nine.size() << endl;
cout << ".. lean: " << nine.lean() << endl;
```

**Output**

[gerry] district:

Making district with one B voter
.. size: 1
.. lean: 1

Making district ABA
.. size: 3
.. lean: -1

Exercise 56.3. Implement a Population class that will initially model a whole state.

**Code:**

```cpp
string pns( "-++--" );
Population some(pns);
cout << "Population from string " << pns << endl;
cout << ".. size: " << some.size() << endl;
cout << ".. lean: " << some.lean() << endl;
Population group=some.sub(1,3);
cout << "sub population 1--3" << endl;
cout << ".. size: " << group.size() << endl;
cout << ".. lean: " << group.lean() << endl;
```

**Output**

[gerry] population:

Population from string -++--
.. size: 5
.. lean: -1
sub population 1--3
.. size: 2
.. lean: 1

In addition to an explicit creation, also write a constructor that specifies how many people and what the majority is:

```cpp
Population( int population_size, int majority, bool trace=false )
```

Use a random number generator to achieve precisely the indicated majority.

56.2.3 Districting

The next level of complication is to have a set of districts. Since we will be creating this incrementally, we need some methods for extending it.

**Exercise 56.4.** Write a class Districting that stores a vector of District objects. Write size and lean methods:
56. Redistricting

Exercise 56.5. Write methods to extend a Districting:

```
cout << "Add one B voter:" << endl;  
gerry = gerry.extend_with_new_district( people.at(0) );  
cout << ". .. number of districts: " << gerry.size() << endl;  
cout << ". .. lean: " << gerry.lean() << endl;  
cout << "add A A:" << endl;  
gerry = gerry.extend_last_district( Voter(1,-1) );  
gerry = gerry.extend_last_district( Voter(2,-1) );  
cout << ". .. number of districts: " << gerry.size() << endl;  
cout << ". .. lean: " << gerry.lean() << endl;  
cout << "Add two B districts:" << endl;  
gerry = gerry.extend_with_new_district( Voter(3,+1) );  
gerry = gerry.extend_with_new_district( Voter(4,+1) );  
cout << ". .. number of districts: " << gerry.size() << endl;  
cout << ". .. lean: " << gerry.lean() << endl;```

56.3 Strategy

Now we need a method for districting a population:

```
Districting Population.minority_rules( int ndistricts );
```

Rather than generating all possible partitions of the population, we take an incremental approach (this is related to the solution strategy called dynamic programming):

- The basic question is to divide a population optimally over \( n \) districts;
- We do this recursively by first solving a division of a subpopulation over \( n - 1 \) districts, and extending that with the remaining population as one district.

This means that you need to consider all the ways of having the ‘remaining’ population into one district, and that means that you will have a loop over all ways of splitting the population, outside of your recursion; see figure 56.1.

- For all \( p = 0, \ldots, n - 1 \) considering splitting the state into \( 0, \ldots, p - 1 \) and \( p, \ldots, n - 1 \).
- Use the best districting of the first group, and make the last group into a single district.
- Keep the districting that gives the strongest minority rule, over all values of \( p \).

You can now realize the above simple example:
Figure 56.1: Multiple ways of splitting a population

\[ AAABB \Rightarrow AAA|B|B \]

Exercise 56.6. Implement the above scheme.

```cpp
Population five("+++--");
cout << "Redistricting population: " << endl;
cout << ". . . . majority rule: " << endl;
int ndistricts{3};
auto gerry = five.minority_rules(ndistricts);
cout << gerry.print() << endl;
cout << ". . . . minority rule: " << endl;
```

Output `[gerry] district5:
Redistricting population:
[0:+,1:+,2:+,3:-,4:-,] .. majority rule: 1
[3[0:+,1:+,2:+,][3:-,],[4:-,],] .. minority rule: -1
```

Note: the range for \( p \) given above is not quite correct: for instance, the initial part of the population needs to be big enough to accommodate \( n - 1 \) voters.
Exercise 56.7. Test multiple population sizes; how much majority can you give party B while still giving party A a majority.

56.4 Efficiency: dynamic programming

If you think about the algorithm you just implemented, you may notice that the districtings of the initial parts get recomputed quite a bit. A strategy for optimizing for this is called memoization.

Exercise 56.8. Improve your implementation by storing and reusing results for the initial sub-populations.

In a way, we solved the program backward: we looked at making a district out of the last so-many voters, and then recursively solving a smaller problem for the first however-many voters. But in that process, we decided what is the best way to assign districts to the first 1 voter, first 2, first 3, et cetera. Actually, for more than one voter, say five voters, we found the result on the best attainable minority rule assigning these five voters to one, two, three, four districts.

The process of computing the ‘best’ districting forward, is known as dynamic programming. The fundamental assumption here is that you can use intermediate results and extend them, without having to reconsider the earlier problems.

Consider for instance that you’ve considered districting ten voters over up to five districts. Now the majority for eleven voters and five districts is the minimum of

- ten voters and five districts, and the new voter is added to the last district; or
- ten voters and four districts, and the new voter becomes a new district.

Exercise 56.9. Code a dynamic programming solution to the redistricting problem.

56.5 Extensions

The project so far has several simplifying assumptions.

- Congressional districts need to be approximately the same size. Can you put a limit on the ratio between sizes? Can the minority still gain a majority?

Exercise 56.10. The biggest assumption is of course that we considered a one-dimensional state. With two dimensions you have more degrees of freedom of shaping the districts. Implement a two-dimensional scheme; use a completely square state, where the census districts form a regular grid. Limit the shape of the congressional districts to be convex.

The efficiency gap is a measure of how ‘fair’ a districting of a state is.
Exercise 56.11. Look up the definition of efficiency gap (and ‘wasted votes’), and implement it in your code.

56.6 Ethics

The activity of redistricting was intended to give people a fair representation. In its degenerate form of Gerrymandering this concept of fairness is violated because the explicit goal is to give the minority a majority of votes. Explore ways that this unfairness can be undone.

In your explorations above, the only characteristic of a voter was their preference for party A or B. However, in practice voters can be considered part of communities. The Voting Rights Act is concerned about ‘minority vote dilution’. Can you show examples that a color-blind districting would affect some communities negatively?
56. Redistricting
Chapter 57

Amazon delivery truck scheduling

This section contains a sequence of exercises that builds up to a simulation of delivery truck scheduling.

57.1 Problem statement

Scheduling the route of a delivery truck is a well-studied problem. For instance, minimizing the total distance that the truck has to travel corresponds to the Traveling Salesman Problem (TSP). However, in the case of Amazon delivery truck scheduling the problem has some new aspects:

• A customer is promised a window of days when delivery can take place. Thus, the truck can split the list of places into sublists, with a shorter total distance than going through the list in one sweep.
• Except that Amazon prime customers need their deliveries guaranteed the next day.

57.2 Coding up the basics

Before we try finding the best route, let’s put the basics in place to have any sort of route at all.

57.2.1 Address list

You probably need a class `Address` that describes the location of a house where a delivery has to be made.

• For simplicity, let give a house $(i,j)$ coordinates.
• We probably need a `distance` function between two addresses. We can either assume that we can travel in a straight line between two houses, or that the city is build on a grid, and you can apply the so-called Manhattan distance.
• The address may also require a field recording the last possible delivery date.

Exercise 57.1. Code a class `Address` with the above functionality, and test it.
57. Amazon delivery truck scheduling
57.2. Coding up the basics

**Code:**

```cpp
Address one(1.,1.),
two(2.,2.);
cerr << "Distance: "
   << one.distance(two)
   << "\n";
```

**Output**

```
[amazon] address:
Address Distance: 1.41421 .. address
Address 1 should be closest to the depot. Check: 1
Route from depot to depot: (0,0) (2,0) (1,0) (3,0) (0,0) has length 8: 8
Greedy scheduling: (0,0) (1,0) (2,0) (3,0) (0,0) should have length 6: 6
Square5
Travel in order: 24.1421
Square route: (0,0) (0,5) (5,5) (5,0) (0,0) has length 20
.. square5
Original list: (0,0) (-2,0) (-1,0) (1,0) (2,0) (0,0) length=8
flip middle two addresses: (0,0) (-2,0) (1,0) (-1,0) (2,0) (0,0) length=12
better: (0,0) (1,0) (-2,0) (-1,0) (2,0) (0,0) length=10
Hundred houses
Route in order has length 25852.6
TSP based on mere listing has length: 2751.99 over naive 25852.6
Single route has length: 2078.43 .. new route accepted with length 2076.65
Final route has length 2076.65 over initial 2078.43
TSP route has length 1899.4 over initial 2078.43
Two routes
Route1: (0,0) (2,0) (3,2) (2,3) (0,2) (0,0)
route2: (0,0) (3,1) (2,1) (1,2) (1,3) (0,0)
total length 19.6251
start with 9.88635,9.73877
Pass 0

.. down to 1747.9,1814.22
```

Victor Eijkhout
Next we need a class `AddressList` that contains a list of addresses.

**Exercise 57.2.** Implement a class `AddressList`; it probably needs the following methods:

- `add_address` for constructing the list;
- `length` to give the distance one has to travel to visit all addresses in order;
- `index_closest_to` that gives you the address on the list closests to another address, presumably not on the list.

### 57.2.2 Add a depot

Next, we model the fact that the route needs to start and end at the depot, which we put arbitrarily at coordinates $(0, 0)$. We could construct an `AddressList` that has the depot as first and last element, but that may run into problems:

- If we reorder the list to minimize the driving distance, the first and last elements may not stay in place.
- We may want elements of a list to be unique: having an address twice means two deliveries at the same address, so the `add_address` method would check that an address is not already in the list.

We can solve this by making a class `Route`, which inherits from `AddressList`, but the methods of which leave the first and last element of the list in place.

### 57.2.3 Greedy construction of a route

Next we need to construct a route. Rather than solving the full TSP, we start by employing a greedy search strategy:

Given a point, find the next point by some local optimality test, such as shortest distance. Never look back to revisit the route you have constructed so far.

Such a strategy is likely to give an improvement, but most likely will not give the optimal route.

Let’s write a method

```cpp
Route::Route greedy_route();
```

that constructs a new address list, containing the same addresses, but arranged to give a shorter length to travel.

**Exercise 57.3.** Write the `greedy_route` method for the `AddressList` class.

1. Assume that the route starts at the depot, which is located at $(0, 0)$. Then incrementally construct a new list by:
2. Maintain an `Address` variable `we_are_here` of the current location;
3. repeatedly find the address closest to `we_are_here`.

Extend this to a method for the `Route` class by working on the subvector that does not contain the final element.
Test it on this example:

```cpp
Route deliveries;
deliveries.add_address( Address(0,5) );
deliveries.add_address( Address(5,0) );
deliveries.add_address( Address(5,5) );
cerr << "Travel in order: " << deliveries.
assert( deliveries.size()==5 );
auto route = deliveries.greedy_route();
assert( route.size()==5 );
auto len = route.length();
cerr << "Square route: " << route.as_string()
    << "\n has length " << len << "\n";
```

Output

> **[amazon]** square5:
>
> Travel in order: 24.1421
> Square route: (0,0) (0,5) (5,5) (5,0) (0,0)
> has length 20

Reorganizing a list can be done in a number of ways.

- First of all, you can try to make the changes in place. This runs into the objection that maybe you want to save the original list; also, while swapping two elements can be done with the `insert` and `erase` methods, more complicated operations are tricky.
- Alternatively, you can incrementally construct a new list. Now the main problem is to keep track of which elements of the original have been processed. You could do this by giving each adress a boolean field `done`, but you could also make a copy of the input list, and remove the elements that have been processed. For this, study the `erase` method for `vector` objects.

### 57.3 Optimizing the route

The above suggestion of each time finding the closest address is known as a greedy search strategy. It does not give you the optimal solution of the TSP. Finding the optimal solution of the TSP is hard to program – you could do it recursively – and takes a lot of time as the number of addresses grows. In fact, the TSP is probably the most famous of the class of NP-hard problems, which are generally believed to have a running time that grows faster than polynomial in the problem size.

![Figure 57.1: Illustration of the ‘opt2’ idea of reversing part of a path](image)

However, you can approximate the solution heuristically. One method, the Kernighan-Lin algorithm [12], is based on the `opt2` idea: if you have a path that ‘crosses itself’, you can make it shorter by reversing part of it. Figure 57.1 shows that the path 1 − − 2 − − 3 − − 4 can be made shorter by reversing part of it, giving 1 − − 3 − − 2 − − 4. Since recognizing where a path crosses itself can be hard, or even impossible for graphs that don’t have Cartesian coordinates associated, we adopt a scheme:
for all nodes m<n on the path [1..N]:
make a new route from
[l..m-1] + [m--n].reversed + [n+1..N]
if the new route is shorter, keep it

Exercise 57.4. Code the opt2 heuristic: write a method to reverse part of the route, and write the loop that tries this with multiple starting and ending points. Try it out on some simple test cases to convince you that your code works as intended.

Exercise 57.5. What is the runtime complexity of this heuristic solution?

Exercise 57.6. Earlier you had programmed the greedy heuristic. Compare the improvement you get from the opt2 heuristic, starting both with the given list of addresses, and with a greedy traversal of it.

57.4 Multiple trucks

If we introduce multiple delivery trucks, we get the ‘Multiple Traveling Salesman Problem’ [5]. With this we can module both the cases of multiple trucks being out on delivery on the same day, or one truck spreading deliveries over multiple days. For now we don’t distinguish between the two.

The first question is how to divide up the addresses.

1. We could split the list in two, using some geometric test. This is a good model for the case where multiple trucks are out on the same day. However, if we use this as a model for the same truck being out on multiple days, we are missing the fact that new addresses can be added on the first day, messing up the neatly separated routes.

2. Thus it may in fact be reasonable to assume that all trucks get an essentially random list of addresses.

Can we extend the opt2 heuristic to the case of multiple paths? For inspiration take a look at figure 57.2: instead of modifying one path, we could switch bits out bits between one path and another. When you write the code, take into account that the other path may be running backwards! This means that based on split points in the first and second path you know have four resulting modified paths to consider.

Exercise 57.7. Write a function that optimizes two paths simultaneously using the multi-path version of the opt2 heuristic. For a test case, see figure 57.3.

You have quite a bit of freedom here:
• The start points of the two segments should be chosen independently;
• the lengths can be chosen independently, but need not; and finally
• each segment can be reversed.
More flexibility also means a longer runtime of your program. Does it pay off? Do some tests and report results.

Based on the above description there will be a lot of code duplication. Make sure to introduce functions and methods for various operations.

57.5 Amazon prime

In section 57.4 you made the assumption that it doesn’t matter on what day a package is delivered. This changes with Amazon prime, where a package has to be delivered guaranteed on the next day.

Exercise 57.8. Explore a scenario where there are two trucks, and each have a number of addresses that can not be exchanged with the other route. How much longer is the total distance? Experiment with the ratio of prime to non-prime addresses.

57.6 Dynamicism

So far we have assumed that the list of addresses to be delivered to is given. This is of course not true: new deliveries will need to be scheduled continuously.
57. Amazon delivery truck scheduling

Exercise 57.9. Implement a scenario where every day a random number of new deliveries is added to the list. Explore strategies and design choices.

57.7 Ethics

People sometimes criticize Amazon’s labor policies, including regarding its drivers. Can you make any observations from your simulations in this respect?
Chapter 58

DNA Sequencing

In this set of exercises you will write mechanisms for DNA sequencing.

58.1 Basic functions

Refer to section 24.4.

First we set up some basic mechanisms.

Exercise 58.1. There are four bases, A, C, G, T, and each has a complement: A ↔ T, C ↔ G. Implement this through a map, and write a function

\[ \text{char BaseComplement(char);} \]

Exercise 58.2. Write code to read a Fasta file into a string. The first line, starting with >, is a comment; all other lines should be concatenated into a single string denoting the genome.

Read the virus genome in the file lambda_virus.fa.

Count the four bases in the genome two different ways. First use a map. Time how long this takes. Then do the same thing using an array of length four, and a conditional statement.

Bonus: try to come up with a faster way of counting. Use a vector of length 4, and find a way of computing the index directly from the letters A, C, G, T. Hint: research ascii codes and possibly bit operations.

58.2 De novo shotgun assembly

One approach to generating a genome is to cut it to pieces, and algorithmically glue them back together. (It is much easier to sequence the bases of a short read than of a very long genome.)

If we assume that we have enough reads that each genome position is covered, we can look at the overlaps by the reads. One heuristic is then to find the SCS! (SCS).
58. DNA Sequencing

58.2.1 Overlap layout consensus
1. Make a graph where the reads are the vertices, and vertices are connected if they overlap; the amount of overlap is the edge weight.
2. The SCS! is then a Hamiltonian path through this graph – this is already NP-complete.
3. Additionally, we optimize for maximum total overlap.
   ⇒ Traveling Salesman Problem (TSP), NP-hard.

Rather than finding the optimal superset, we can use a greedy algorithm, where every time we find the read with maximal overlap.

Repeats are often a problem. Another is spurious subgraphs from sequencing errors.

58.2.2 De Bruijn graph assembly

58.3 ‘Read’ matching

A ‘read’ is a short fragment of DNA, that we want to match against a genome. In this section you will explore algorithms for this type of matching.

While here we mostly consider the context of genomics, such algorithms have other applications. For instance, searching for a word in a web page is essentially the same problem. Consequently, there is a considerable history of this topic.

58.3.1 Naive matching

We first explore a naive matching algorithm: for each location in the genome, see if the read matches up.

```
ATACTGACCAAGAACGTGATTACTTCATGCAGCGTTACCAT
ACCAAGAACGTG
```

```
° mismatch

ATACTGACCAAGAACGTGATTACTTCATGCAGCGTTACCAT
ACCAAGAACGTG
```

```
total match
```

Exercise 58.3. Code up the naive algorithm for matching a read. Test it on fake reads obtained by copying a substring from the genome. Use the genome in phix.fa.

Now read the Fastq file ERR266411_1.first1000.fastq. Fastq files contains groups of four lines: the second line in each group contains the reads. How many of these reads are matched to the genome?

Reads are not necessarily a perfect match; in fact, each fourth line in the fastq file gives an indication of the ‘quality’ of the corresponding read. How many matches do you get if you take a substring of the first 30 or so characters of each read?
58.3.2 Boyer-Moore matching

The Boyer-Moore string matching algorithm [6] is much faster than naive matching, since it uses two clever tricks to weed out comparisons that would not give a match.

Bad character rule

In naive matching, we determined match locations left-to-right, and then tried matching left-to-right. In BM! (BM!), we still find match locations left-to-right, but we do our matching right-to-left.

```
vvvv match location
antidisestablishmentarianism
blis
`bad character
```

The mismatch is an ‘l’ in the pattern, which does not match a ‘d’ in the text. Since there is no ‘d’ in the pattern at all, we move the pattern completely past the mismatch:

```
vvvv match location
antidisestablishmentarianism
blis
```

in fact, we move it further, to the first match on the first character of the pattern:

```
vvvv match location
antidisestablishmentarianism
blis
^ first character match
```

The case where we have a mismatch, but the character in the text does appear in the pattern is a little trickier: we find the next occurrence of the mismatched character in the pattern, and use that to determine the shift distance.

```
shoobeedoobeboobah
edoobeboob
` mismatch
^ other occurrence of `d`
```

Note that this can be a considerably smaller shift than in the previous case.

```
shoobeedoobeboobah
edoobeboob
` match the bad character `d`
^ new location
```

Exercise 58.4. Discuss how efficient you expect this heuristic to be in the context of genomics versus text searching. (See above.)
**Good suffix rule**

The ‘good suffix’ consists of the matched characters after the bad character. When moving the read, we try to keep the good suffix intact:

```
  desistrust
  listrest
  `good suffix`
```

```
  desistrust
  listrest
  `next occurrence of suffix`
```
Chapter 59

High performance linear algebra

Linear algebra operations such as the matrix-matrix product are easy to code in a naive way. However, this does not lead to high performance. In these exercises you will explore the basics of a strategy for high performance.

59.1 Mathematical preliminaries

The matrix-matrix product \( C \leftarrow A \cdot B \) is defined as

\[
\forall_{ij} : c_{ij} \leftarrow \sum_k a_{ik} b_{kj}.
\]

Straightforward code for this would be:

```c
for (i=0; i<a.m; i++)
  for (j=0; j<b.n; j++)
    s = 0;
  for (k=0; k<a.n; k++)
    s += a[i,k] * b[k,j];
  c[i,j] = s;
```

However, this is not the only way to code this operation. The loops can be permuted, giving a total of six implementations.

Exercise 59.1. Code one of the permuted algorithms and test its correctness. If the reference algorithm above can be said to be ‘inner-product based’, how would you describe your variant?

Yet another implementation is based on a block partitioning. Let \( A, B, C \) be split on \( 2 \times 2 \) block form:

\[
A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \quad B = \begin{pmatrix} B_{11} & B_{12} \\ B_{21} & B_{22} \end{pmatrix}, \quad C = \begin{pmatrix} C_{11} & C_{12} \\ C_{21} & C_{22} \end{pmatrix}
\]

Then

\[
\begin{align*}
C_{11} &= A_{11}B_{11} + A_{12}B_{21}, \\
C_{12} &= A_{11}B_{12} + A_{12}B_{22}, \\
C_{21} &= A_{21}B_{11} + A_{22}B_{21}, \\
C_{22} &= A_{21}B_{12} + A_{22}B_{22}
\end{align*}
\] (59.1)

(Convince yourself that this actually computes the same product \( C = A \cdot B \).)
59. High performance linear algebra

59.2 Matrix storage

The simplest way to store an $M \times N$ matrix is as an array of length $MN$. Inside this array we can decide to store the rows end-to-end, or the columns. Historically, linear algebra software has used columnwise storage, meaning that the location of an element $(i,j)$ is computed as $j + i \cdot M$ (we will use zero-based indexing throughout this project, both for code and mathematical expressions.)

Above, you saw the idea of block algorithms, which requires taking submatrices. For efficiency, we don’t want to copy elements into a new array, so we want the submatrix to correspond to a subarray.

Now we have a problem: only a submatrix that consists of a sequence of columns is contiguous. For this reason, linear algebra software treats each matrix like a submatrix, described by three parameters $M, N, LDA$, where ‘LDA’ stands for ‘leading dimension of $A$’ (see Basic Linear Algebra Subprograms (BLAS) [10], and Lapack [1]). This is illustrated in figure 59.1.

![Figure 59.1: Submatrix out of a matrix, with m,n,lda of the submatrix indicated](image)

Exercise 59.2. In terms of $M, N, LDA$, what is the location of the $(i,j)$ element?

Implementationwise we also have a problem. If we use `std::vector` for storage, it is not possible to take subarrays, since C++ insists that a vector has its own storage. The solution is to use `span`; section 11.8.5.

We could have two types of matrices: top level matrices that store a `vector<double>`, and submatrices that store a `span<double>`, but that is a lot of complication. It could be done using `std::variant` (section 24.5.3), but let’s not.

Instead, let’s adopt the following idiom, where we create a vector at the top level, and then create matrices from its memory.

```cpp
// example values for M,LDA,N
M = 2; LDA = M+2; N = 3;
```
// create a vector to contain the data
vector<double> one_data(LDA*N,1.);
// create a matrix using the vector data
Matrix one(M, LDA, N, one_data.data());

(If you have not previously programmed in C, you need to get used to the `double*` mechanism. Read up on section 11.8.2.)

**Exercise 59.3.** Start implementing the `Matrix` class with a constructor

```cpp
Matrix::Matrix(int m, int lda, int n, double *data)
```

and private data members:

```cpp
private:
    int m, n, lda;
    span<double> data;
```

Write a method

```cpp
double& Matrix::at(int i, int j);
```

that you can use as a safe way of accessing elements.

Let’s start with simple operations.

**Exercise 59.4.** Write a method for adding matrices. Test it on matrices that have the same $M, N$, but different $LDA$.

Use of the `at` method is great for debugging, but it is not efficient. Use the preprocessor (chapter 21) to introduce alternatives:

```cpp
#ifdef DEBUG
    c.at(i, j) += a.at(i, k) * b.at(k, j)
#else
    cdata[ /* expression with i, j */ ] += adata[ ... ] * bdata[ ... ]
#endif
```

where you access the data directly with

```cpp
auto get_double_data() {
    double *adata;
    adata = data.data();
    return adata;
}
```

**Exercise 59.5.** Implement this. Use a cpp `#define` macro for the optimized indexing expression. (See section 21.2.3.)
59. High performance linear algebra

59.2.1 Submatrices

Next we need to support constructing actual submatrices. Since we will mostly aim for decomposition in $2 \times 2$ block form, it is enough to write four methods:

```cpp
Matrix Left(int j);
Matrix Right(int j);
Matrix Top(int i);
Matrix Bot(int i);
```

where, for instance, $\text{Left}(5)$ gives the columns with $j < 5$.

**Exercise 59.6.** Implement these methods and test them.

59.3 Multiplication

You can now write a first multiplication routine, for instance with a prototype

```cpp
void Matrix::MatMult( Matrix& other, Matrix& out );
```

Alternatively, you could write

```cpp
Matrix Matrix::MatMult( Matrix& other );
```

but we want to keep the amount of creation/destruction of objects to a minimum.

59.3.1 One level of blocking

Next, write

```cpp
void Matrix::BlockedMatMult( Matrix& other, Matrix& out );
```

which uses the $2 \times 2$ form above.

59.3.2 Recursive blocking

The final step is to make the blocking recursive.

**Exercise 59.7.** Write a method

```cpp
void RecursiveMatMult( Matrix& other, Matrix& out );
```

which

- Executes the $2 \times 2$ block product, using again `RecursiveMatMult` for the blocks.
- When the block is small enough, use the regular `MatMult` product.
59.4 Performance issues

If you experiment a little with the cutoff between the regular and recursive matrix-matrix product, you see that you can get good factor of performance improvement. Why is this?

The matrix-matrix product is a basic operation in scientific computations, and much effort has been put into optimizing it. One interesting fact is that it is just about the most optimizable operation under the sum. The reason for this is, in a nutshell, that it involves $O(N^3)$ operations on $O(N^2)$ data. This means that, in principle each element fetched will be used multiple times, thereby overcoming the memory bottleneck.

Exercise 59.8. Read up on cache memory, and argue that the naive matrix-matrix product implementation is unlikely actually to reuse data.

Explain why the recursive strategy does lead to data reuse.

Above, you set a cutoff point for when to switch from the recursive to the regular product.

Exercise 59.9. Argue that continuing to recurse will not have much benefit once the product is contained in the cache. What are the cache sizes of your processor?

Do experiments with various cutoff points. Can you relate this to the cache sizes?

59.4.1 Parallelism (optional)

The four clauses of equation 59.1 target independent areas in the $C$ matrix, so they could be executed in parallel on any processor that has at least four cores.

Explore the OpenMP library to parallelize the `BlockedMatMult`.

59.4.2 Comparison (optional)

The final question is: how close are you getting to the best possible speed? Unfortunately you are still a way off. You can explore that as follows.

Your computer is likely to have an optimized implementation, accessible through:

```c
#include <cblas.h>

cblas_dgemm( 
  CblasColMajor, CblasNoTrans, CblasNoTrans, 
  m, other.n, n, alpha, adata, lda, 
  bdata, other lda, 
  beta, cdata, out lda);
```

which computes $C \leftarrow \alpha A \cdot B + \beta C$. 

Victor Eijkhout

437
Exercise 59.10. Use another cpp conditional to implement \texttt{MatMult} through a call to \texttt{cblas_dgemm}. What performance do you now get?

You see that your recursive implementation is faster than the naive one, but not nearly as fast as the CBlas one. This is because

- the CBlas implementation is probably based on an entirely different strategy \cite{9}, and
- it probably involves a certain amount of assembly coding.

Chapter 62

Climate change

The climate has changed and it is always changing.
Raj Shah, White House Principal Deputy Press Secretary

The statement that climate always changes is far from a rigorous scientific claim. We can attach a meaning to it, if we interpret it as a statement about the statistical behaviour of the climate, in this case as measured by average global temperature. In this project you will work with real temperature data, and do some simple analysis on it. (The inspiration for this project came from [11].)

Ideally, we would use data sets from various measuring stations around the world. Fortran is then a great language because of its array operations (see chapter 39): you can process all independent measurements in a single line. To keep things simple we will use a single data file here that contains data for each month in a time period 1880-2018. We will then use the individual months as ‘pretend’ independent measurements.

62.1 Reading the data

In the repository you find two text files

GLB.Ts+dSST.txt  GLB.Ts.txt

that contain temperature deviations from the 1951–1980 average. Deviations are given for each month of each year 1880–2018. These data files and more can be found at https://data.giss.nasa.gov/gistemp/.

Exercise 62.1. Start by making a listing of the available years, and an array monthly_deviation of size $12 \times \text{nyears}$, where nyears is the number of full years in the file. Use formats and array notation. The text files contain lines that do not concern you. Do you filter them out in your program, or are you using a shell script? Hint: a judicious use of grep will make the Fortran code much easier.
62. Climate change

62.2 Statistical hypothesis

We assume that Mr Shah was really saying that climate has a ‘stationary distribution’, meaning that highs and lows have a probability distribution that is independent of time. This means that in \( n \) data points, each point has a chance of \( 1/n \) to be a record high. Since over \( n + 1 \) years each year has a chance of \( 1/(n+1) \), the \( n + 1 \)st year has a chance \( 1/(n+1) \) of being a record.

We conclude that, as a function of \( n \), the chance of a record high (or low, but let’s stick with highs) goes down as \( 1/n \), and that the gap between successive highs is approximately a linear function of the year\(^1\).

This is something we can test.

**Exercise 62.2.** Make an array `previous_record` of the same shape as `monthly_deviation`. This array records (for each month, which, remember, we treat like independent measurements) whether that year was a record, or, if not, when the previous record occurred:

\[
\text{PrevRec}(m, y) = \begin{cases} 
  y & \text{if } \text{MonDev}(m, y) = \max_{m'}(\text{MonDev}(m', y)) \\
  y' & \text{if } \text{MonDev}(m, y) < \text{MonDev}(m, y') \\
  \text{and } \text{MonDev}(m, y') = \max_{m'' < m'}(\text{MonDev}(m'', y))
\end{cases}
\]

Again, use array notation. This is also a great place to use the `Where` clause.

**Exercise 62.3.** Now take each month, and find the gaps between records. This gives you two arrays: `gapyears` for the years where a gap between record highs starts, and `gapsizes` for the length of that gap.

This function, since it is applied individually to each month, uses no array notation.

The hypothesis is now that the `gapsizes` are a linear function of the year, for instance measured as distance from the starting year. Of course they are not exactly a linear function, but maybe we can fit a linear function through it by *linear regression*.

**Exercise 62.4.** Copy the code from [http://www.aip.de/groups/soe/local/numres/bookfpdf/f15-2.pdf](http://www.aip.de/groups/soe/local/numres/bookfpdf/f15-2.pdf) and adapt for our purposes: find the best fit for the slope and intercept for a linear function describing the gaps between records.

You’ll find that the gaps are decidedly not linearly increasing. So is this negative result the end of the story, or can we do more?

---

1. Technically, we are dealing with a uniform distribution of temperatures, which makes the maxima and minima have a beta-distribution.
Exercise 62.5. Can you turn this exercise into a test of global warming? Can you interpret the deviations as the sum of a yearly increase in temperature plus a stationary distribution, rather than a stationary distribution by itself?
62. Climate change
PART VI

ADVANCED TOPICS
Chapter 63

External libraries

If you have a C++ compiler, you can write as much software as you want, by yourself. However, some things that you may need for your work have already been written by someone else. How can you use their software?

63.1 What are software libraries?

In this chapter you will learn about the use of software libraries: software that is written not as a standalone package, but in such a way that you can access its functionality in your own program.

Software libraries can be enormous, as is the case for scientific libraries, which are often multi-person multi-year projects. On the other hand, many of them are fairly simple utilities written by a single programmer. In the latter case you may have to worry about future support of that software.

63.1.1 Using an external library

Using a software library typically means that

• your program has a line

```c
#include "fancylib.h"
```

• and you compile and link as:

```bash
icpc -c yourprogram.cxx -I/usr/include/fancylib  
icpc -o yourprogram yourprogram.o -L/usr/lib/fancylib -lfancy
```

You will see specific examples below.

If you are now worried about having to do a lot of typing every time you compile,

• if you use an IDE, you can typically add the library in the options, once and for all; or
• you can use Make for building your program. See the tutorial.
63. External libraries

63.1.2 Obtaining and installing an external library

Sometimes a software library is available through a package manager, but we are going to do it the old-fashioned way: downloading and installing it ourselves.

A popular location for finding downloadable software is `github.com`. You can then choose whether to
• clone the repository, or
• download everything in one file, typically with `.tgz` or `.tar.gz` extension; in that case you need to unpack it
  ```
  tar fxz fancylib.tgz
  ```

This usually gives you a directory with a name such as `fancylib-1.0.0` containing the source and documentation of the library, but not any binaries or machine-specific files.

Either way, from here on we assume that you have a directory containing the downloaded package.

There are two main types of installation:
• based on GNU autotools, which you recognize by the presence of a `configure` program;
  ```
  cmake ## lots of options
  make
  make install
  ```
  or
• based on Cmake, which you recognize by the presence of `CMakeLists.txt` file:
  ```
  configure ## lots of options
  make
  make install
  ```

63.1.2.1 Cmake installation

The easiest way to install a package using `cmake` is to create a build directory, next to the source directory. The `cmake` command is issued from this directory, and it references the source directory:

```
mkdir build
cd build
cmake ../fancylib-1.0.0
make
make install
```

Some people put the build directory inside the source directory, but that is bad practice.

Apart from specifying the source location, you can give more options to `cmake`. The most common are
• specifying an install location, for instance because you don’t have `superuser` privileges on that machine; or
Some random libraries

63.2.1 Options processing: cxxopts

Suppose you have a program that does something with a large array, and you want to be able to change your mind about the array size. You could

- You could recompile your program every time.
- You could let your program parse argv, and hope you remember precisely how your command-line options are to be interpreted.
- You could use the cxxopts library. This is what we will be exploring now.

The cxxopts `commandline argument parser` can be found at https://github.com/jarro2783/cxxopts. After a Cmake installation, it is a ‘header-only’ library.

- Include the header

```cpp
#include "cxxopts.hpp"
```

which requires a compile option:

```cpp
-I/path/to/cxxopts/installdir/include
```

- Declare an options object:

```cpp
cxxopts::Options options("programname", "Program description");
```

- Add options:

```cpp
options.add_options()
  ("h,help","usage information")
  ("n,nsize","size of the thing",
   cxxopts::value<int>()->default_value("4096"))
  // et cetera
```

- Parse the options:

```cpp
auto result = options.parse(argc, argv);
```

- Get result values:

```cpp
if (result.count("help")>0) {
  std::cout << options.help() << std::endl;
  return 0;
}
int array_size = result["nsizes"].as<int>();
```

Options can be specified the usual ways:
63. External libraries

myprogram -n 10
myprogram --nsize 100
myprogram --nsize=1000
Chapter 64

Programming strategies

64.1 A philosophy of programming

Code for the reader, not the writer

Yes, your code will be executed by the computer, but:
• You need to be able to understand your code a month or year from now.
• Someone else may need to understand your code.
• ⇒ make your code readable, not just efficient

High level and low level

• Don’t waste time on making your code efficient, until you know that that time will actually pay off.
• Knuth: ‘premature optimization is the root of all evil’.
• ⇒ first make your code correct, then worry about efficiency

Abstraction

• Variables, functions, objects, form a new ‘language’:
  code in the language of the application.
• ⇒ your code should look like it talks about the application, not about memory.
• Levels of abstraction: implementation of a language should not be visible on the use level of that language.

64.2 Programming: top-down versus bottom up

The exercises in chapter 52 were in order of increasing complexity. You can imagine writing a program that way, which is formally known as bottom-up programming.

However, to write a sophisticated program this way you really need to have an overall conception of the structure of the whole program.

Maybe it makes more sense to go about it the other way: start with the highest level description and gradually refine it to the lowest level building blocks. This is known as top-down programming.

https://www.cs.fsu.edu/~myers/c++/notes/stepwise.html

Example:
64. Programming strategies

Run a simulation
becomes
Run a simulation:
    Set up data and parameters
    Until convergence:
        Do a time step
becomes
Run a simulation:
    Set up data and parameters:
        Allocate data structures
        Set all values
    Until convergence:
        Do a time step:
            Calculate Jacobian
            Compute time step
            Update

You could do these refinement steps on paper and wind up with the finished program, but every step that is refined could also be a subprogram.

We already did some top-down programming, when the prime number exercises asked you to write functions and classes to implement a given program structure; see for instance exercise 52.9.

A problem with top-down programming is that you can not start testing until you have made your way down to the basic bits of code. With bottom-up it’s easier to start testing. Which brings us to...

64.2.1 Worked out example

Take a look at exercise 6.14. We will solve this in steps.

1. State the problem:
   // find the longest sequence

2. Refine by introducing a loop
   // find the longest sequence:
       // Try all starting points
       // If it gives a longer sequence report

3. Introduce the actual loop:
   // Try all starting points
   for (int starting=2; starting<1000; starting++) {
       // If it gives a longer sequence report
   }

4. Record the length:
   // Try all starting points
   int maximum_length=-1;
64.3 Coding style

After you write your code there is the issue of code maintenance: you may in the future have to update your code or fix something. You may even have to fix someone else’s code or someone will have to work on your code. So it’s a good idea to code cleanly.

**Naming** Use meaningful variable names: `record_number` instead `rn` or `n`. This is sometimes called ‘self-documenting code’.

**Comments** Insert comments to explain non-trivial parts of code.

**Reuse** Do not write the same bit of code twice: use macros, functions, classes.

64.4 Documentation

Take a look at Doxygen.

64.5 Best practices: C++ Core Guidelines

The C++ language is big, and some combinations of features are not advisable. Around 2015 a number of Core Guidelines were drawn up that will greatly increase code quality. Note that this is not about performance: the guidelines have basically no performance implications, but lead to better code.
For instance, the guidelines recommend to use default values as much as possible when dealing with multiple constructors:

```cpp
class Point { // not this way
private:
    double d;
public:
    Point( double x, double y, double fudge ) {
        auto d = ( x*x + y*y ) * (1+fudge); }
    Point( double x, double y ) {
        auto d = ( x*x + y*y ); }
};
```

This is bad because of code duplication. Slightly better:

```cpp
class Point { // not this way
private:
    double d;
public:
    Point( double x, double y, double fudge ) {
        auto d = ( x*x + y*y ) * (1+fudge); }
    Point( double x, double y ) : Point(x,y,0.) {};
};
```

which wastes a couple of cycles if fudge is zero. Best:

```cpp
class Point { // not this way
private:
    double d;
public:
    Point( double x, double y, double fudge=0. ) {
        auto d = ( x*x + y*y ) * (1+fudge); }
};
```
Chapter 65

Tiniest of introductions to algorithms and data structures

65.1 Data structures

The main data structure you have seen so far is the array. In this section we briefly sketch some more complicated data structures.

65.1.1 Stack

A stack is a data structure that is a bit like an array, except that you can only see the last element:
• You can inspect the last element;
• You can remove the last element; and
• You can add a new element that then becomes the last element; the previous last element becomes invisible: it becomes visible again as the last element if the new last element is removed.

The actions of adding and removing the last element are known as push and pop respectively.

Exercise 65.1. Write a class that implements a stack of integers. It should have methods

```java
void push(int value);
int pop();
```

65.1.2 Linked lists

Before doing this section, make sure you study section 16.

Arrays are not flexible: you can not insert an element in the middle. Instead:
• Allocate a larger array,
• copy data over (with insertion),
• delete old array storage

This is expensive. (It’s what happens in a C++ `vector`; section 11.3.2.)

If you need to do lots of insertions, make a linked list. The basic data structure is a Node, which contains
1. Information, which can be anything; and
2. A pointer (sometimes called ‘link’) to the next node. If there is no next node, the pointer will be
null. Every language has its own way of denoting a null pointer; C++ has the nullptr, while
C uses the NULL which is no more than a synonym for the value zero.

We illustrate this in figure 65.1.

Our main concern will be to implement operations that report some statistic of the list, such as its length,
that test for the presence of information in the list, or that alter the list, for instance by inserting a new
node. See figure 65.2.

65.1.2.1 Data definitions

In C++ you have a choice of pointer types. Conceptually we can say that the list object owns the first
node, and each node owns the next. Therefore we use the unique_ptr; however, you can also use
shared_ptr throughout, at slight overhead cost.

We declare the basic classes.

**Definition of List class**

A linked list has as its only member a pointer to a node:

```cpp
class List {
    private:
        unique_ptr<Node> head(nullptr);
    public:
        List() {};
}
```

Initially null for empty list.
65.1. Data structures

Definition of Node class
A node has information fields, and a link to another node:

```cpp
class Node {
friend class List;
private:
  int datavalue(0), datacount(0);
  unique_ptr<Node> next(nullptr);
public:
friend class List;
Node() {}  // Node constructor
Node(int value, unique_ptr<Node> tail nullptr) :
  datavalue(value), datacount(1), next(move(tail)) { };
  ~Node() { cout \texttt{\textasciitilde} \textquotesingle; \textasciitilde\textasciitilde; deleting node \textasciitilde\textquotesingle; datavalue \textasciitilde\textasciitilde; };
}
```

A Null pointer indicates the tail of the list.

65.1.2 Simple functions
For many algorithms we have the choice between an iterative and a recursive version. The recursive version is easier to formulate, but the iterative solution is probably more efficient.

Recursive computation of the list length

```cpp
int recursive_length() {
if (head==nullptr)  // base case
  return 0;
else
  return head->listlength();
}
```

```cpp
int listlength_recursive() {
if (!has_next()) return 1;
else return 1+next->listlength();
}
```

The structure of an iterative version is intuitively clear: we have a pointer that goes down the list, incrementing a counter at every step. There is one complication: with C++ smart pointers, the variable that contains the current element can not be a unique pointer.

Iterative computation of the list length

Use a bare pointer, which is appropriate here because it doesn’t own the node.

```cpp
int listlength_iterative() {
  int count = 0;
  Node *current_node = head.get();
  while (current_node!=nullptr) {
    current_node = current_node->next.get(); count += 1;
  }
  return count;
}
```

(You will get a compiler error if you try to make current_node a smart pointer: you can not copy a unique pointer.)

Victor Eijkhout 459
Exercise 65.2. Write a function

```
bool List::contains_value(int v);
```

to test whether a value is present in the list.
Try both recursive and iterative.

65.1.2.3 Modification functions

The interesting methods are of course those that alter the list. Inserting a new value in the list has basically two cases:

1. If the list is empty, create a new node, and set the head of the list to that node.
2. If the list is not empty, we have several more cases, depending on whether the value goes at the head of the list, the tail, somewhere in the middle. And we need to check whether the value is already in the list.

Our choice of using unique pointers dictates a certain design.

**Insert routine design**

We will write functions

```
void List::insert(int value);
void Node::insert(int value);
```

that add the value to the list. The `List::insert` value can put a new node in front of the first one; the `Node::insert` assumes the the value is on the current node, or gets inserted after it.

There are a lot of cases here. You can try this by an approach called Test-Driven Development (TDD): first you decide on a test, then you write the code that covers that case.

**Step 1: dealing with an empty list**

Exercise 65.3. Write a `List::length` method, so that this code gives the right output:

```
List mylist;
cout << "Empty list has length: "
    << mylist.listlength_iterative() << endl;
cout << endl;
```
65.1. Data structures

Step 2: insert the first element

Exercise 65.4. Next write the case of `Node::insert` that handles the empty list. You also need a method `List::contains` that tests if an item if in the list.

```cpp
mylist.insert(3);
cout << "After one insertion the length is: "
    << mylist.listlength_iterative() << endl;
if (mylist.contains_value(3))
    cout << "Indeed: contains 3" << endl;
else
    cout << "Hm. Should contain 3" << endl;
if (mylist.contains_value(4))
    cout << "Hm. Should not contain 4" << endl;
else
    cout << "Indeed: does not contain 4" << endl;
```

Step 3: inserting an element that already exists

Exercise 65.5. Inserting a value that is already in the list means that the `count` value of a node needs to be increased. Update your `insert` method to make this code work:

```cpp
mylist.insert(3);
cout << "Inserting the same item gives length: "
    << mylist.listlength_iterative() << endl;
if (mylist.contains_value(3)) {
    cout << "Indeed: contains 3" << endl;
    auto headnode = mylist.headnode();
    cout << "head node has value " << headnode->value() 
        << " and count " << headnode->count() << endl;
} else
    cout << "Hm. Should contain 3" << endl;
```

Victor Eijkhout
65. Tiniest of introductions to algorithms and data structures

**Step 4: inserting an element before another**

Exercise 65.6. One of the remaining cases is inserting an element that goes at the head. Update your `insert` method to get this to work:

```cpp
mylist.insert(2);
cout << "Inserting 2 goes at the head; now the length is: "
    << mylist.listlength_iterative() << endl;
if (mylist.contains_value(2))
    cout << "Indeed: contains 2" << endl;
else
    cout << "Hm. Should contain 2" << endl;
if (mylist.contains_value(3))
    cout << "Indeed: contains 3" << endl;
else
    cout << "Hm. Should contain 3" << endl;
cout << endl;
```

**Step 5: inserting an element at the end**

Exercise 65.7. Finally, if an item goes at the end of the list:

```cpp
mylist.insert(4);
cout << "Inserting 4 goes at the tail; now the length is: "
    << mylist.listlength_iterative() << endl;
if (mylist.contains_value(4))
    cout << "Indeed: contains 4" << endl;
else
    cout << "Hm. Should contain 4" << endl;
if (mylist.contains_value(3))
    cout << "Indeed: contains 3" << endl;
else
    cout << "Hm. Should contain 3" << endl;
cout << endl;
```
65.1. Data structures

65.1.3 Trees

Before doing this section, make sure you study section 16.

A tree can be defined recursively:
• A tree is empty, or
• a tree is a node with some number of children trees.

Let’s design a tree that stores and counts integers: each node has a label, namely an integer, and a count
value that records how often we have seen that integer.

Our basic data structure is the node, and we define it recursively to have up to two children. This is a
problem: you can not write

```c++
class Node {
private:
    Node left, right;
}
```
because that would recursively need infinite memory. So instead we use pointers.

```c++
class Node {
private:
    int key{0}, count{0};
    shared_ptr<Node> left, right;
    bool hasleft{false}, hasright{false};
public:
    Node() {} 
    Node(int i, int init=1) { key = i; count = 1; };
    void addleft(int value) {
        left = make_shared<Node>(value);
        hasleft = true;
    };
    void addright(int value) {
        right = make_shared<Node>(value);
        hasright = true;
    };
    /* ... */
};
```
and we record that we have seen the integer zero zero times.

Algorithms on a tree are typically recursive. For instance, the total number of nodes is computed from
the root. At any given node, the number of nodes of that attached subtree is one plus the number of nodes
of the left and right subtrees.

```c++
int number_of_nodes() {
    int count = 1;
    if (hasleft)
        count += left->number_of_nodes();
    if (hasright)
        count += right->number_of_nodes();
    return count;
};
```
Likewise, the depth of a tree is computed as a recursive max over the left and right subtrees:
int depth() {
    int d = 1, dl=0, dr=0;
    if (hasleft)
        dl = left->depth();
    if (hasright)
        dr = right->depth();
    d = max(d+dl, d+dr);
    return d;
}

Now we need to consider how actually to insert nodes. We write a function that inserts an item at a node. If the key of that node is the item, we increase the value of the counter. Otherwise we determine whether to add the item in the left or right subtree. If no such subtree exists, we create it; otherwise we descend in the appropriate subtree, and do a recursive insert call.

```c
void insert(int value) {
    if (key==value)
        count ++;
    else if (value<key) {
        if (hasleft)
            left->insert(value);
        else
            addleft(value);
    } else if (value>key) {
        if (hasright)
            right->insert(value);
        else
            addright(value);
    } else throw(1); // should not happen
}
```

### 65.2 Algorithms

This really really goes beyond this book.

- Simple ones: numerical
- Connected to a data structure: search

#### 65.2.1 Sorting

Unlike the tree algorithms above, which used a non-obvious data structure, sorting algorithms are a good example of the combination of very simple data structures (mostly just an array), and sophisticated analysis of the algorithm behaviour. We very briefly discuss two algorithms.

#### 65.2.1.1 Bubble sort

An array $a$ of length $n$ is sorted if

$$\forall i<n-1: a_i \leq a_{i+1}.$$

A simple sorting algorithm suggests itself immediately: if $i$ is such that $a_i > a_{i+1}$, then reverse the $i$ and $i+1$ locations in the array.
void swapij(vector<int> &array, int i) {
    int t = array[i];
    array[i] = array[i+1];
    array[i+1] = t;
}

(Why is the array argument passed by reference?)

If you go through the array once, swapping elements, the result is not sorted, but at least the largest
element is at the end. You can now do another pass, putting the next-largest element in place, and so on.

This algorithm is known as bubble sort. It is generally not considered a good algorithm, because it has
a time complexity (section 69.1.1) of $n^2/2$ swap operations. Sorting can be shown to need $O(n \log n)$
operations, and bubble sort is far above this limit.

65.2.1.2 Quicksort

A popular algorithm that can attain the optimal complexity (but need not; see below) is quicksort:
• Find an element, called the pivot, that is approximately equal to the median value.
• Rearrange the array elements to give three sets, consecutively stored: all elements less than,
equal, and greater than the pivot respectively.
• Apply the quicksort algorithm to the first and third subarrays.

This algorithm is best programmed recursively, and you can even make a case for its parallel execution:
every time you find a pivot you can double the number of active processors.

Exercise 65.8. Suppose that, by bad luck, your pivot turns out to be the smallest array element every
time. What is the time complexity of the resulting algorithm?

65.3 Programming techniques

65.3.1 Memoization

In section 7.5 you saw some examples of recursion. The factorial example could be written in a loop,
and there are both arguments for and against doing so.

The Fibonacci example is more subtle: it can not immediately be converted to an iterative formulation,
but there is a clear need for eliminating some waste that comes with the simple recursive formulation.
The technique we can use for this is known as memoization: store intermediate results to prevent them
from being recomputed.

Here is an outline.

```cpp
int fibonacci(int n) {
    vector<int> fibo_values(n);
    for (int i=0; i<n; i++)
        fibo_values[i] = 0;
    fibonacci_memoized(fibo_values, n-1);
    return fibo_values[n-1];
}
```
65. Tiniest of introductions to algorithms and data structures

```cpp
int fibonacci_memoized(vector<int> &values, int top) {
    int minus1 = top-1, minus2 = top-2;
    if (top<2)
        return 1;
    if (values[minus1]==0)
        values[minus1] = fibonacci_memoized(values,minus1);
    if (values[minus2]==0)
        values[minus2] = fibonacci_memoized(values,minus2);
    values[top] = values[minus1]+values[minus2];
    //cout << "set f(" << top << ") to " << values[top] << endl;
    return values[top];
}
```
Chapter 66

Provably correct programs

Programming often seems more an art, even a black one, than a science. Still, people have tried systematic approaches to program correctness. One can distinguish between

- proving that a program is correct, or
- writing a program so that it is guaranteed to be correct.

This distinction is only imaginary. A more fruitful approach is to let the proof drive the coding. As E.W. Dijkstra pointed out

> The only effective way to raise the confidence level of a program significantly is to give a convincing proof of its correctness. But one should not first make the program and then prove its correctness, because then the requirement of providing the proof would only increase the poor programmer’s burden. On the contrary: the programmer should let correctness proof and program grow hand in hand.

We will see a couple of examples of this.

66.1 Loops as quantors

Quite often, algorithms can be expressed mathematically. In that case you should make your program look like the mathematics.

66.1.1 Forall-quantor

Consider a simple example: testing if a number is prime. The predicate \( \text{isprime} \) can be expressed as:

\[
\text{isprime}(n) \equiv \forall_{2 \leq f < n} \neg \text{divides}(f, n)
\]

We now spell out the ‘for all’ quantor iteratively as a loop where each iteration needs to be true. That is, we do an ‘and’ reduction on some iteration-dependent result.

\[
\neg \text{divides}(2, n) \cap \ldots \cap \neg \text{divides}(n - 1, n)
\]

And this sequence of ‘and’ conjunctions can be programmed:

```cpp
for (int f=2; f<n; f++)
    isprime = isprime && not divides(f, p)
```

Now our only worry is how to initialize isprime. The initial value corresponds to an ‘and’ conjunction over an empty set, which is true, so:

```cpp
bool isprime(true);
for (int f=2; f<n; f++)
    isprime = isprime & not divides(f,p)
```

### 66.1.2 Thereis-quantor

What if we had expressed primeness as:

\[ \text{isprime}(n) \equiv \neg \exists_{2 \leq f < n} \text{divides}(f,n) \]

To get a pure quantor, and not a negated one, we write:

\[ \text{isnotprime}(n) \equiv \exists_{2 \leq f < n} \text{divides}(f,n) \]

Spelling out the exists-quantor as

\[ \text{isnotprime}(n) \equiv \text{divides}(2, n) \cup \ldots \cup \text{divides}(n-1, n) \]

we see that we need a loop where we test if any iteration satisfies a predicate. That is, we do an ‘or’-reduction on the results of each iteration.

```cpp
for (int f=2; f<n; f++)
    isnotprime = isnotprime or divides(f,p)
bool isprime = not isnotprime;
```

Again we take care to initialize the reduction variable correctly: applying \( \exists_{s \in S} P(s) \) over an empty set \( S \) is \( \text{false} \):

```cpp
for (int f=2; f<n; f++)
    isnotprime = isnotprime or divides(f,p)
bool isprime = not isnotprime;
```

### 66.2 Predicate proving

For programs that have a clear loop structure you can take an approach that is similar to doing a ‘proof by induction’.

Let us consider the Collatz conjecture again, where for brevity we define

\[ c(\ell) = \text{the length of the Collatz sequences, starting on } \ell. \]

Now we consider the Collatz conjecture as proving a predicate

\[
P(\ell_k, m_k, k) = \begin{cases} 
\ell_k < k \\
\land \ c(\ell_k) = m_k \text{(only if } k > 0) \\
\land \ \forall_{\ell<k} \ c(\ell) \leq m_k 
\end{cases}
\]

for \( k = N \).

We develop the code that makes this predicate inductively true. We start out with

\[
\ell_0 = -1, \quad m_0 = 0 \Rightarrow P(\ell_0, m_0, 0).
\]

The inductive proof corresponds to a loop:

```cpp
```
we assume that at the start of the $k$-th iteration $P(\ell, m, k)$ is true;
the iteration body is such that at the end of the $k$-th iteration $P(\ell_{k+1}, m_{k+1}, k + 1)$ is true;
this of course sets up the predicate at the start of the next iteration.

The loop structure is then:

\[
\begin{align*}
\text{k} = 0; \\
\{ P(l, m, k) \} \\
\text{while} ( \ k < N \ ) \ { \ \\
\{ P(l, m, k) \} \\
\text{update;} \\
\{ P(\ell_{k+1}, m_{k+1}, k + 1) \} \\
\text{k} = k + 1; \\
\}
\end{align*}
\]

The update has to extend the predicate from $k$ to $k + 1$. Let us consider the parts of it.

We need to establish

\[
\forall \ell < k+1 : c(\ell) \leq m_{k+1}
\]

We split the range $\ell < k + 1$ into $\ell < k$ and $\ell = k$:

- the first part

\[
\forall \ell < k : c(\ell) \leq m_{k+1}
\]

is true if $m_{k+1} \geq m_k$;

- the part

\[
\ell = k : c(\ell) \leq m_{k+1}
\]

states that $m_{k+1} \geq c(k)$.
Together we get that

\[
m_{k+1} \geq \max(m_k, c(k))
\]

Finally, the clause

\[
c(\ell_{k+1}) = m_{k+1}
\]

can be satisfied:

- If $c(k) > m_k$, we need to set $m_{k+1} = c(k)$ and $\ell_{k+1} = k$.
- (Strictly speaking, there is a possibility $m_{k+1} > c(k)$. This is not possible, because we can not satisfy $m_{k+1} = c(\ell_k)$ for any $k$.)
- If $c(k) \leq m_k$, we need to set $m_{k+1} \geq m_k$. Again, $m_{k+1} > m_k$ can not be satisfied by any $\ell_{k+1}$, so we conclude $m_{k+1} = m_k$. 
66. Provably correct programs
Chapter 67

Unit testing and Test-Driven Development

In an ideal world, you would prove your program correct, but in practice that is not always feasible, or at least: not done. Most of the time programmers establish the correctness of their code by testing it.

Yes, there is a quote by Edsger Dijkstra that goes:

> Today a usual technique is to make a program and then to test it. But: program testing can be a very effective way to show the presence of bugs, but is hopelessly inadequate for showing their absence. (cue laughter)

but that doesn’t mean that you can’t at least gain some confidence in your code by testing it.

### 67.1 Types of tests

Testing code is an art, even more than writing the code to begin with. That doesn’t mean you can’t be systematic about it. First of all, we distinguish between some basic types of test:

- **Unit tests** that test a small part of a program by itself;
- **System tests** test the correct behavior of the whole software system; and
- **Regression tests** establish that the behavior of a program has not changed by adding or changing aspects of it.

In this section we will talk about unit testing.

A program that is written in a sufficiently modular way allows for its components to be tested without having to wait for an all-or-nothing test of the whole program. Thus, testing and program design are aligned in their interests. In fact, writing a program with the thought in mind that it needs to be testable can lead to cleaner, more modular code.

In an extreme form of this you would write your code by **TCC! (TCC!)**: for each part of the program you would first write the test that it would satisfy, and then you write the actual code.

### 67.2 Unit testing frameworks

There are several ‘frameworks’ that help you with unit testing. In the remainder of this chapter we will use **Catch2**, which is one of the most used ones in C++.

You can find the code at [https://github.com/catchorg](https://github.com/catchorg).
The easiest strategy is to have a file without a `main` and only unit tests; Catch2 supplies the main.

The next thing is what header file to include. You can do

```
#include "catch.hpp"
```

but that makes compilation very slow. Therefore, we will assume you have installed Catch through Cmake, giving you a setup with separate header and library files.

**Unit test driver file**

```
#define CATCH_CONFIG_MAIN
#include "catch2/catch_all.hpp"
#include "yourprogram.h"

/*
here follow the unit tests
*/
```

This design requires you to add compile and link flags to your setup. This is system-dependent.

**Compile and link options**

```
INCLUDES = -I${TACC_CATCH2_INC}
EXTRALIBS = -L${TACC_CATCH2_LIB} -lCatch2 -lCatch2main
```

A test case is a short program that is run as an independent main. You can name your test case, which helps when errors are printed, and you can give keys that allow you to select tests from the commandline.

```
TEST_CASE( "name of this test","[key1][key2]" ) {
   // stuf
}
```

The body of the test case is a program where some statements are encapsulated in test macros. The most common macro is `REQUIRE`, which is used to demand correctness of some condition.

**Require correctness**

- `TEST_CASE` acts like independent program.
- Can contain (multiple) tests for correctness.

```
TEST_CASE( "test that f always returns positive","[key1][key2]" ) {
   for (int n=0; n<1000; n++)
      REQUIRE( f(n)>0 );
}
```

If your code throws exceptions (section 23.2.2) you can test for these.

**Test for exceptions**

```
TEST_CASE( "test that g only works for positive","[key1][key2]" ) {
   for (int n=-100; n<+100; n++)
      if (n<=0)
         REQUIRE_THROWS( g(n) );
      else
         REQUIRE_NOTHROW( g(n) );
}
```
A common occurrence in unit testing is to have multiple tests with a common setup or teardown, to use terms that you sometimes come across in unit testing. Catch2 supports this: you can make ‘sections’ for part in between setup and teardown.

### Setup and teardown

```cpp
TEST_CASE("commonalities","[key1][key2]")
{
// common setup:
double x, y, z;
REQUIRE_NOTHROW( y = f(x) );
// two independent tests:
SECTION( "g function" )
{
  REQUIRE_NOTHROW( z = g(y) );
}
SECTION( "h function" )
{
  REQUIRE_NOTHROW( z = h(y) );
}
// common followup
REQUIRE( z>x );
}
```

### 67.3 An example: the eight queens problem

Let’s revisit the eight queens exercise of section 7.9.1, and tackle it with unit tests. The basic strategy will be that we fill consecutive rows, by indicating each time which column will be occupied by the next queen.

Using an Object-Oriented (OO) strategy, we make a class placement with a constructor that only indicates the size of the problem:

```cpp
placement(int n);
```

We have an auxiliary function that states what the next row to be filled is:

```cpp
int next_row_to_be_filled() const;
```

This gives us our first trivial test:

```cpp
TEST_CASE( "empty placement","[constructor]")
{
constexpr int n=10;
placement empty(n);
REQUIRE(empty.next_row_to_be_filled()==0);
}
```

(From now on we’ll only give the body of the test here.)

Next, we have a function to place the next queen, whether this gives a feasible board or not: missing snippet placementdonext

This test should catch incorrect indexing:

```cpp
auto one(empty);
REQUIRE_THROWS( one.place_next_queen_at_column(-1) );
REQUIRE_THROWS( one.place_next_queen_at_column(n) );
REQUIRE_NOTHROW( one.place_next_queen_at_column(0) );
REQUIRE( one.next_row_to_be_filled()==1 );
```
(Suppose you didn’t test for incorrect indexing. Can you construct a simple ‘cheating’ solution at any size?)

But it’s time to write some serious stuff. If you have a placement, even partial, you want to test if it’s feasible:

```cpp
bool feasible() const;
```

This test has to work for simple cases to begin with. You can add these lines to the above tests:

```cpp
REQUIRE(empty.feasible());
REQUIRE(one.feasible());
```

We shouldn’t only do successfull tests. If we put two queens in the same column, the test should fail. Take the above initial attempt with a queen in position (0, 0):

```cpp
auto collide(one);
collide.place_next_queen_at_column(0);
REQUIRE(!collide.feasible());
```

Can you write tests that detect such collision for all columns?

If we want to test the feasibility of non-trivial configurations it is a good idea be able to ‘create’ solutions. For this we need a second constructor:

```cpp
placement(vector<int> cols);
```

Now we test small solutions:

```cpp
placement five({0,3,1,4,2});
REQUIRE(five.feasible());
```

But ultimately we have to write the tricky stuff. The recursive function

```cpp
optional<placement> place_queen(const placement& current);
```

is up to you.

(The function `optional` is discussed in section 24.5.2; alternative you could make your recursive function

```cpp
bool place_queen(const placement& current, placement& next);
// true if possible, false is not
```

or so.)

Because it is recursive it is a little hard to test. You can at least test that, if you almost have the solution, it can do the last step:

```cpp
placement almost({1,3,0,place_empty});
auto solution = place_queen(almost);
REQUIRE(solution.has_value());
REQUIRE(solution->filled());
```

And you can test that there are no $3 \times 3$ solutions:
67.3. An example: the eight queens problem

```cpp
TEST_CASE( "no 3x3 solutions","" ) {
    placement three(3);
    auto solution = place_queen(three);
    REQUIRE( not solution.has_value() );
}

but 4 × 4 solutions do exist:

```cpp
TEST_CASE( "there are 4x4 solutions","" ) {
    placement four(4);
    auto solution = place_queen(four);
    REQUIRE( solution.has_value() );
}
```
67. Unit testing and Test-Driven Development
Chapter 68

Debugging with gdb

We are going to use the following simple program:

```c
void say(int n) {
    cout << "hello world " << n << endl;
}

int main() {
    for (int i=0; i<10; i++) {
        int ii;
        ii = i*i;
        ii++;
        say(ii);
    }
    return 0;
}
```

68.1 Invoking the debugger

After you compile your program, instead of running it the normal way, you invoke `gdb`:

```
gdb myprogram
```

That puts you in an environment, recognizable by the `(gdb)` prompt:

```
GNU gdb (GDB) Red Hat Enterprise Linux 7.6.1-115.el7
[stuff]
(gdb)
```

where you can do a controlled run of your program with the `run` command:

```
(gdb) run
Starting program: /home/eijkhout/gdb/hello
hello world 1
hello world 2
hello world 5
hello world 10
```
68. Debugging with `gdb`

```plaintext
hello world 17
hello world 26
hello world 37
hello world 50
hello world 65
hello world 82
[Inferior 1 (process 30981) exited normally]
```

### 68.1.1 Run with commandline arguments

This program is self-contained, but if you had a program that takes `commandline arguments`:

```bash
./myprogram 25
```

you can supply those in `gdb`:

```bash
(gdb) run 25
```

### 68.1.2 Source listing and proper compilation

Inside `gdb`, you can get a source listing with the `list` command.

Let's try our program again:

```bash
[] icpc -o hello hello.cxx
[] gdb hello
GNU gdb (GDB) Red Hat Enterprise Linux 7.6.1-115.el7
Copyright (C) 2013 Free Software Foundation, Inc.
Reading symbols from /home/eijkhout/gdb/hello...
   (no debugging symbols found)...
done.
(gdb) list
No symbol table is loaded. Use the "file" command.
```

See the repeated reference to ‘symbols’? You need to supply the `-g` compiler option for the `symbol table` to be included in the binary:

```bash
[] icpc -g -o hello hello.cxx
[] gdb hello
GNU gdb (GDB) Red Hat Enterprise Linux 7.6.1-115.el7
[stuff]
Reading symbols from /home/eijkhout/gdb/hello...done.
(gdb) list
13   using std::cout;
14   using std::endl;
[et cetera]
```
(If you hit return now, the list command is repeated and you get the next block of lines. Doing list -gives you the block above where you currently are.)

### 68.2 Stepping through the source

Let’s now make a more controlled run of the program. In the source, we see that line 22 is the first executable one:

```c
20    int main() {
21
22    for (int i=0; i<10; i++) {
23        int ii;
24        ii = i*i;
```

We introduce a **breakpoint** with the `break` command:

```
(gdb) break 22
Breakpoint 1 at 0x400a03: file hello.cxx, line 22.
```

(If your program is spread over multiple files, you can specify the file name: `break otherfile.cxx:34`.)

Now if we run the program, it will stop at that line:

```
(gdb) run
Starting program: /home/eijkhout/gdb/hello
Breakpoint 1, main () at hello.cxx:22
22    for (int i=0; i<10; i++) {
```

To be precise: the program is stopped in the state before it executes this line.

We can now use `cont` (for ‘continue’) to let the program run on. Since there are no further breakpoints, the program will run to completion. This is not terribly useful, so let us change our minds about the location of the breakpoint: it would be more useful if the execution stopped at the start of every iteration.

Recall that the breakpoint had a number of 1, so we use `delete` to remove it, and we set a breakpoint inside the loop body instead, and continue until we hit it.

```
(gdb) delete 1
(gdb) break 23
Breakpoint 2 at 0x400a29: file hello.cxx, line 23.
(gdb) cont
Continuing.
Breakpoint 2, main () at hello.cxx:23
24    ii = i*i;
```

(Note that line 23 is not executable, so execution stops on the first line after that.)

Now if we continue, the program runs until the next break point:
68. Debugging with gdb

```
(gdb) cont
Continuing.
hello world 5

Breakpoint 1, main () at hello.cxx:24
24     ii = i*i;

To get to the next statement, we use `next`:

```
(gdb) next
25     ii++;
(gdb)
```

Hitting return re-executes the previous command, so we go to the next line:

```
(gdb)
26     say(ii);
(gdb)
hello world 2

Breakpoint 1, main () at hello.cxx:24
24     ii = i*i;
```

You observe that the function call
1. is executed, as is clear from the `hello world 1` output, but
2. is not displayed in detail in the debugger.

The conclusion is that `next` goes to the next executable statement in the current subprogram, not into functions and such that get called from it.

If you want to go into the function `say`, you need to use `step`:

```
(gdb) next
25     ii++;
(gdb) next
26     say(ii);
(gdb) step
say (n=10) at hello.cxx:17
17     cout << "hello world " << n << endl;
```

The debugger reports the function name, and the names and values of the arguments. Another ‘step’ executes the current line and brings us to the end of the function, and the next ‘step’ puts us back in the main program:

```
(gdb)
hello world 10
18 }
(gdb)
main () at hello.cxx:24
24     ii = i*i;
```
68.3 Inspecting values

When execution is stopped at a line (remember, that means right before it is executed!) you can inspect any values in that subprogram:

```
ii = i*i;
(gdb) print i
$1 = 4
```

You can even let expressions be evaluated with local variables:

```
(gdb) print 2*i
$2 = 8
```

You can combine this looking at values with breakpoints. Say you want to know when the variable `ii` gets more than 40:

```
(gdb) break 26 if ii>40
Breakpoint 1 at 0x4009cd: file hello.cxx, line 26.
(gdb) run
Starting program: /home/eijkhout/intro-programming-private/code/gdb/hello
hello world 1
hello world 2
hello world 5
hello world 10
hello world 17
hello world 26
hello world 37

Breakpoint 1, main () at hello.cxx:26
26 say(ii);
Missing separate debuginfos, use: debuginfo-install glibc-2.17-292.el7.x86_64 libgcc-4.8.5-39.el7.x86_64 libstdc++-4.8.5-39.el7.x86_64
(gdb) print i
$1 = 7
```

68.4 A NaN example

The following program:

```
float root(float n)
{
    float r;
    float n1 = n-1.1;
    r = sqrt(n1);
    return r;
}

int main() {
    float x=9,y;
```
prints some numbers that are ‘not-a-number’:

```
[ ] ./root
root: 2.81069
root: 2.60768
root: 2.38747
root: 2.14476
root: 1.87083
root: 1.54919
root: 1.14018
root: 0.447214
root: -nan
root: -nan
root: -nan
```

Suppose you want to figure out why this happens.

The line that prints the ‘nan’ is 29, so we want to set a breakpoint there, and preferably a conditional breakpoint. But how do you test on ‘nan’? This takes a little trick.

```
(gdb) break 29 if y!=y
Breakpoint 1 at 0x400ea6: file root.cxx, line 28.
(gdb) run
Starting program: /home/eijkhout/intro-programming-private/code/gdb/root
root: 2.81069
root: 2.60768
root: 2.38747
root: 2.14476
root: 1.87083
root: 1.54919
root: 1.14018
root: 0.447214
root: -nan
root: -nan
root: -nan
```

We discover what iteration this happens:

```
(gdb) print i
$1 = 8
```

```
for (int i=0; i<20; i++) {
  y = root(x);
  cout << "root: " << y << endl;
  x -= 1.1;
}
return 0;
```
so now we can rerun the program, and investigate that particular iteration:

```plaintext
(gdb) break 28 if i==8
Breakpoint 2 at 0x400eaf: file root.cxx, line 28.
(gdb) run
The program being debugged has been started already.
Start it from the beginning? (y or n) y
Starting program: /home/eijkhout/intro-programming-private/code/gdb/root
root: 2.81069
root: 2.60768
root: 2.38747
root: 2.14476
root: 1.87083
root: 1.54919
root: 1.14018
root: 0.447214

Breakpoint 2, main () at root.cxx:28
28 y = root(x);
```

We now go into the `root` routine to see what is going wrong there:

```plaintext
(gdb) step
root (n=0.200000554) at root.cxx:20
20 float n1 = n-1.1;
(gdb)
21 r = sqrt(n1);
(gdb) print n
$2 = 0.200000554
(gdb) print n1
$3 = -0.89999944
(gdb) next
22 return r;
(gdb) print r
$4 = -nan(0x400000)
```

And there we have the problem: our input $n$ is used to compute another number $n1$ of which we compute the square root, and sometimes this number gets negative.

### 68.5 Assertions

Instead of running a program and debugging it if you happen to spot a problem (and note that this may not always be the case!) you can also make your program more robust by including assertions. These are things that you know should be true, from your knowledge of the problem you are solving.
For instance, in the previous example there was a square root function, and you just ‘knew’ that the input was always going to be positive. So you edit your program as follows:

```c
// header to allow assertions:
#include <cassert>

float root(float n)
{
    float r;
    float n1 = n-1.1;
    assert(n1>=0); // NOTE!
    r = sqrt(n1);
    return r;
}
```

Now if you run your program, you get:

```
[...]
./assert
root: 2.81069
root: 2.60768
root: 2.38747
root: 2.14476
root: 1.87083
root: 1.54919
root: 1.14018
root: 0.447214
Aborted (core dumped)
```

What does this give you?

- It only tells you that an assertion failed, not with what values;
- it does not give you a traceback or so; on the other hand
- assertions can help you detect error conditions that you might otherwise have overlooked!
Chapter 69

Complexity

69.1 Order of complexity

69.1.1 Time complexity

Exercise 69.1. For each number \( n \) from 1 to 100, print the sum of all numbers 1 through \( n \).

There are several possible solutions to this exercise. Let’s assume you don’t know the formula for the sum of the numbers 1 \ldots n. You can have a solution that keeps a running sum, and a solution with an inner loop.

Exercise 69.2. How many operations, as a function of \( n \), are performed in these two solutions?

69.1.2 Space complexity

Exercise 69.3. Read numbers that the user inputs; when the user inputs zero or negative, stop reading. Add up all the positive numbers and print their average.

This exercise can be solved by storing the numbers in a \texttt{std::vector}, but one can also keep a running sum and count.

Exercise 69.4. How much space do the two solutions require?
